acid with six times its quantity of water, and applied it as a fomentation to the mortified part, after making deep scarifications. In this manner he stopped, or seemed to stop, a mortification, arising from a violent inflammation of the scrotum and penis, and which extended all over these parts. The same author strongly recommends the same topical application to the sloughy state of the gums in cases of scurvy. In this kind of case, he mixed the muriatic acid with honey, in various proportions; sometimes, he even employed the pure acid itself for touching the parts, which were likely to slough. It is easy to comprehend, that the muriatic acid, as well as other mineral acids, and vinegar, weakened with a sufficient quantity of water, may act as an antiphlogistic, and antiseptic; but, when it is concentrated, its manner of acting is then very different, as it is a real caustic, and its salutary effects can only be explained by the change, which it produces in the nature of the inflammation, which now becomes favourable to the formation of the healthy pus.

It is only in the same way, that we can account for the good effects, attributed to another, much more active caustic, than the muriatic acid, namely, a solution of mercury in the nitrous acid, with which solution the edges of the mortified part are recommended to be wet. This, it is said, stops the progress of mortification. We are not, however, possessed of a sufficient number of facts in support of such practice. An example mentioned by a judicious author, Mr. Kirkland, deserves attention.

A man met with a fracture of the forearm, and the ends of the bones projected through the integuments. The fracture was very expeditiously reduced; but, at the end of five, or six days, the whole arm seemed to be completely mortified up to the shoulder. Amputation was performed as near the joint as possible, and the stump, which had mortified as far as the acromion, was cauterised. The following day the mortification had reached the inferior extremity of the scapula. A little of the solution of mercury in nitrous acid was now applied, by means of a probe, along the edges of the parts affected, and from this moment the disorder made no further progress. This cauterisation was repeated every day, for seventeen, or eighteen days. The sloughs, and even the scapula itself, were detached, and the patient got well.

On the continent, liquid caustics are sometimes used as topical applications to gangrenous diseases, more especially, however, in cases of hospital gangrene, and malignant carbuncle. Of this last disorder, M. Larrey has recorded a very dangerous example, in which he effected a cure by first cutting away as much of the sloughs

as possible, and then applying to the disorganized surface underneath liquid caustics. Under the use of emollients, two persons had already fallen victims to the disease in the same family. (See *Mémoires de Chirurgie Militaire*, Tom. 1, p. 53.)

With respect to the actual cautery, Celsus has recommended it to be applied to the line, which separates the dead parts from those which are still living, whenever medicines, and, particularly, topical emollient applications fail in stopping the progress of the disorder. M. Pouteau ventured to revive this practice, which had been entirely exploded from modern surgery, and he was of opinion, that the method might have the most beneficial effects, in cases of erysipelatous gangrene, which is so often seen in hospitals, in consequence of wounds. For this purpose, he recommends cauterizing chiefly the edges of such parts, as are of a dark red colour, and are on the point of perishing; and he advises this to be done with a heated iron, or boiling oil, and to repeat the cauterisation of the dead parts, at every time of dressing them, until the sensation of heat is even felt with a certain degree of force in the sound parts. The whole of the affected part is afterwards to be covered with a large emollient poultice.

M. Pouteau relates a very interesting case of an anthrax, which took place on a woman's cheek, and which he cured in the above manner. The tumour, which, on the third day, was quite black, and as large as a walnut, was accompanied with an erysipelatous œdema, which extended over the whole cheek, eyelids, and front of the neck. M. Pouteau, after having opened the tumour in different directions with a lancet, introduced the red-hot cautery, and repeated the application several times, until the heat was felt by the sound flesh. The patient felt herself very much relieved immediately after this had been done; an oppressive headach, and a very afflicting sense of strangulation, which she had before experienced, were got rid of, and, in ten days more, the slough was detached on the occurrence of suppuration. (*Encyclopédie Méthodique, Partie Chirurgicale, Art. Gangrene.*)

But, perhaps, of all the species of mortification, the hospital gangrene is that, for which the use of caustics and the actual cautery itself, has had the most numerous and respectable advocates. The heated iron is even now employed by the first surgeons of Paris for this particular case. (See *Sketches of the Medical Schools of Paris* by J. Cross, p. 84.) This subject, however, is particularly considered in another article. (See *Hospital Gangrene.*)

The foregoing observations are introduced into this work, that the reader may not be left entirely ignorant of what vie-

lent measures have been adopted in cases of mortification, and the account is not given, in order that such practice may be again imitated. The employment of these terrible applications, viz. the actual cautery, and boiling oils, is as unscientific, and unnecessarily painful, as it is unproductive of any essential good. The grand object in almost every case of mortification, is to diminish the irritation of the parts in immediate contact with those already dead. This is indicated, lest the parts still alive, and so situated, should experience the same fate, as the contiguous ones. Some who have reprobated the application of spirituous and resinous substances to parts affected with mortification, and who have also condemned incisions and scarifications, give their approbation to the use of the cautery. They assert, that the manner, in which the latter acts, is essentially different from that, in which spirituous and resinous applications operate, and that while these, by irritating the affected parts, tend to increase and propagate the inflammation, that leads to mortification, the lively action of the cautery changes the nature of such inflammation, and establishes that state of the vessels, which is necessary for a favourable suppuration. They state, also, that the cautery gives a tone to the vessels, in the vicinity of the parts to which it is applied, and, in proof of this remark, they refer to the effects of the application on different ill-conditioned ulcers, and particularly, on carious bones. (*Encyclopédie Methodique, Partie Chirurgicale, Art. Gangrene.*)

Notwithstanding these assertions, I shall venture to congratulate the surgeons of this country in particular, on the total rejection of the use of the actual cautery and boiling oils, in cases of mortification.

MOXA (Japanese). A soft lanuginous substance prepared from the young leaves of a species of mugwort. It is used in the following way: A little cone of the moxa is laid upon the part, previously moistened, and set on fire at the top. It burns down with a temperate glowing heat, and produces a dark-coloured spot, the separation of which is promoted by applying a little garlic. The ulcer is left to discharge, or is healed up according to the object in view. The moxa is famous in the East for curing several diseases; and the French are much in the habit of using it; but, whenever English surgeons wish to produce a slough, they have recourse to caustics, in preference to actual fire.

M. Roux, when he lately visited the London hospitals, had two opportunities afforded him of applying the moxa, in order to convince the rising generation of surgeons in this country of its superior efficacy. The first was in a case of spontaneous paralysis of the deltoid muscle at *St. Bartholomew's*. The moxa was applied a little below the acromion, and a few days afterwards the motion of the arm began to be restored. This, however, was a case, which, according to the account of *M. Roux* himself, had relapsed, after having been cured by other means. I think one of the surgeons of *St. Bartholomew's* informed me some time ago, that notwithstanding the moxa, the relief proved again only temporary. If, however, the moxa had succeeded, a caustic issue, a blister, or volatile liniments, would probably have answered equally well. The second instance, in which *M. Roux* applied the moxa, was a case of white swelling at *Guy's Hospital*; but, the disease had advanced too far to allow any hope of a favourable issue. (See *Voyage fait à Londres en 1814*, ou

Parallèle de la Chirurgie Angloise avec la Chirurgie Française, p. 19—20.) M. Roux flatters himself that, "*les chirurgiens Anglois répugneront sans doute moins à l'avenir à faire usage du moxa.*" The truth is, English surgeons, as well as English farriers, knew very well before the arrival of M. Roux what might be done with moxa and the actual cautery. But, though the application of fire still prevails in the veterinary art, as a mode of curing diseases, it has long been abandoned as a means of relief in the English practice of surgery; not on the ground of its being always ineffectual; but, because equal good has been found to result from measures, which are milder, always

less terrific, and frequently less painful. In order to convince an English surgeon that moxa and the actual cautery ought to be introduced into practice, M. Roux should prove, that there is at least some particular disease, which may in this manner be cured, but, which cannot be cured by other means ordinarily employed in our practice. He should also make us forget, that the application of actual fire was once as common in English surgery as in French; but that it had not attractions enough to maintain its ground.

MYDRIASIS. (from *μυδαν*, to abound in moisture.) A preternatural dilatation of the pupil.

N.

NÆVUS. (*Congenitæ Notæ*; *Envies*; *Mutter-mahl*; *Mother-spots*, &c.) A mole, or congenital mark, or excrescence of the skin. *Nævi materni* signify the little spots, excrescences, or swellings, with which many children are born. Some of them (says Dr. Bateman) are merely superficial, or stain-like spots, and appear to consist of a partial thickening of the rete mucosum, sometimes of a yellow, or yellowish brown, sometimes of a blueish, livid, or nearly black colour. To these the term *spilus* has been more particularly appropriated. Others again exhibit various degrees of thickening, elevation, and altered structure of the skin itself, and consist of clusters of enlarged and contorted veins, freely anastomosing, and forming little sacs of blood. These are sometimes spread more or less extensively over the surface, occasionally covering even the whole of an extremity, or one half of the trunk of the body; and sometimes they are elevated into prominences of various form and magnitude. Occasionally, these marks are nearly of the usual colour of the skin; but, most commonly they are of a purplish red colour, of varying degrees of intensity; such as the presence of a considerable collection of blood-vessels, situated near the surface, and covered with a thin cuticle, naturally occasions. (See *Bateman's Practical Synopsis of Cutaneous Diseases*, p. 324. Edit. 3.) When a *nævus* is of a dark red colour, its intensity is generally augmented by every thing, which tends to accelerate the circulation of the blood. Fits of anger, hot weather, fevers, and the period of menstruation, in particular, are observed to be attended with an increased turgescence and discoloration of the part affected. Indeed, the excrescence sometimes bursts, and pours out a dangerous quantity of blood, and in females it has been known to become the seat of a regular

menstrual discharge. (*Boyer, Traité des Maladies Chir. T. 2, p. 277*; and *John Bell's Principles, Discourse 9.*) Some *nævi*, especially those usually called *moles*, frequently have long, irregular hairs growing upon them; while the surface of others is streaked, and even granulated. Such as appear in the form of a mere red, purplish stain, have been absurdly supposed to arise from a desire for claret, or some other wine of that colour, entertained by the mother of the patient during her pregnancy. The granulated *nævi* have been compared with raspberries, strawberries, mulberries, &c. for which the mother's longing is ascribed by the vulgar as a cause. The truth is, however, that this doctrine, imputing the origin of *nævi* to fancies of the mother, is neither consistent with experience, nor sound physiology. The causes (as Callisen observes) "*potius autem in evolutione primorum flaminum, a naturæ solita via aberrante, uti in aliis rebus monstrosis quærendæ erunt.*" (*Syst. Chir. Hodiernæ, Vol. 2, p. 201.*)

From what has been said, then, it appears, that certain *nævi* are merely cutaneous spots, of a red, violet, or purplish colour, of greater or lesser extent, and with scarcely any perceptible elevation. They are an organic malformation of the skin, the natural texture of which does not exist, but has substituted for it a plexus of vessels, not endued with the natural sensibility of the cutis itself. These *nævi* generally continue stationary during life, and may be regarded rather as a deformity, than a disease. (*Lassus, Pathologie Chir. Tom. 1, p. 477.*) Other *nævi* are either of the same nature as the disease, well known by the name of the "*aneurism by anastomosis*," or bear a considerable resemblance to it. They are sometimes of great size; and their shape is subject to much variety. They are soft, and inde-

lent, and of a violet, or dark red colour. The skin which covers them is very thin, and when they are opened, their structure is like that of a spleen, whose blood-vessels are varicose. Some are covered with a delicate white skin, and do not increase with age. Others are more disposed to grow large. These tumours frequently occur in the skin of the face, and in other parts of the integuments, on the inside of the labia pudendi, and cheeks, and in the substance of the upper and lower lip, where they sometimes form a kind of elongation, attended with great disfigurement. Nævi of this kind, so situated in new-born infants, may produce a serious obstacle to the action of sucking. M. A. Severinus has particularly described them under the appellation of "tuberculum atro-cruentum labii inferioris." (*De Abscessuum natura*, Cap. 29, p. 303.)

The nævi, which form in the subcutaneous cellular substance, and were named by Petit "loupes variqueuses," (*Œuvres Posthumes*, Tom. 1, p. 276.) are also of the same nature as the aneurism by anastomosis. In time, these attain a very large size. Mr. Latta says, he once saw in a child, two years old, a tumour of this kind, weighing fourteen ounces, which, at the time of birth, was only equal in size to a large bean. During the first year, it did not enlarge much; but it afterwards grew rapidly to the size already specified. (*System of Surgery*, Vol. 2, Chap. 22.) Lassus has even seen a tumour of this description as large as a man's head. (*Pathologie Chir.* Tom. 1, p. 479.) Having treated particularly of the "aneurism by anastomosis," in another place (see *Aneurism*), I shall merely repeat the necessity there is for cutting every particle of the disease away, every portion of the congeries of vessels and cells of which it consists, whenever it is meddled with at all. Puncturing the swelling, or the partial removal of it, has cost many persons their lives by hemorrhage, as the records of surgery fully prove. (*Petit Traité des Maladies Chir.* Tom. 1; *Lassus, Pathologie Chir.* Tom. 1, p. 484, &c.)

Although the original causes of nævi are buried in obscurity, experience proves, that whatever produces irritation in the part affected, or an increased determination of blood to it, has generally the effect of accelerating the growth and enlargement of the swelling. Thus, a trifling bruise, or a tight hat, will sometimes excite a mere stain-like speck, or a minute livid tubercle, into that diseased action, which occasions its growth. (*Bateman's Pract. Synopsis*, &c. p. 327, Edit. 3.)

With regard to the treatment of nævi, the subject may be explained in a few words. When these marks, or swellings, are superficial, without any disposition to enlarge, or spread, and their trivial eleva-

tion does not expose them to accidental rupture, there appears to be no good reason for interfering with them. Indeed, they could only be destroyed with caustic, or the knife, and these severe means would leave scars, accompanied with nearly the same degree of disfigurement.

But, as a valuable writer observes, when nævi evince a tendency to enlarge, or are very prominent excrescences, and either troublesome from their situation, or liable to be ruptured, either their growth must be repressed by sedative applications, or the whole congeries of vessels extirpated with the knife. Mr. Abernethy has proposed the application of cold washes, and the pressure of a bandage. This practice was found by him in several instances to have the desired effect of checking the growth of the tumors, which afterwards shrunk, and became no longer objects of any consequence. (See *Abernethy's Surgical Works*, Vol. 2, p. 224.) Boyer also knew of a case, in which a nævus of the upper lip was cured by the mother pressing the part with her finger unremittingly for seven hours at a time, and the use of an alum wash. (*Traité des Maladies Chir.* Tom. 2, p. 269.) Boyer, however, is not generally an advocate for this mode of treatment; and Dr. Bateman expressly states, that, in the majority of cases, pressure is the source of great irritation to these maculæ, and cannot be employed. (P. 329.)

For all those examples, which partake of the nature of the aneurism by anastomosis, and are disposed to grow, the best general mode of cure is extirpation with the knife. The prudence of this practice, and the necessity of taking away every particle of the disease, has been already explained: this is what was advised by F. Hildanus; (*Cent. 5, Obs. 46.*) what was strongly urged by the celebrated Petit, (*Œuvres Posthumes*, Tom. 1.); what was recommended in still more animated terms by Mr. John Bell, (*Principles of Surgery*, Discourse 9;) and it is what is particularly insisted upon in another part of this Dictionary. See *Aneurism*.

In general, stimulating applications cannot be made to nævi, without risk of exasperating, instead of lessening them. Mere thickenings, and discolorations of the rete mucosum, however, have sometimes been removed by a mixture of spirit and the liquor potassæ. (*Bateman*, p. 330.)

Formerly caustic was much in vogue for the removal of nævi; but, unless its action extend deeply enough to destroy every part of the disease, it may cause a dangerous degree of irritation, copious hemorrhages, and a sudden and fatal enlargement of the tumor. Therefore, as it is a more painful measure than the knife, and less certain in its effects, it should be on every account discarded from practice. It cannot be de-

nied, however, that the old surgeons had success with their caustics, where the nævi were altogether superficial. Thus, in speaking of caustic remedies, Callisen observes: "inter quæ eximio cum successu adhibetur sapo cum æquali parte calcis vivæ subtilissimæ commixtus, nævo per emplastrum perforatum admovendus, et alio emplastro imposito firmandus; hoc remedio eschara inurit, qua soluta, cicatrix alba remanere solet." (*Syst. Chirurgiæ Hodiernæ*, Vol. 2, p. 202.)

NECROSIS. (from *νέκρω*, to destroy.) This word, the strict meaning of which is only mortification, is, by the general consent of surgeons, confined to this affection of the bones. It was first used in this particular sense, by the celebrated M. Louis, who restricted its application, however, to examples, in which the whole thickness of a bone was destroyed. (See *Mém. de l'Acad. Royale de Chirurgie*, Tom. 5, 4to.) By the ancients, the death of parts of bones was not distinguished from caries. However, necrosis and caries are essentially different; for, in the first, the affected part of the bone is deprived of the vital principle; but this is not the case when it is simply carious. Caries is very analogous to ulceration, while necrosis closely resembles mortification, of the soft parts.

Between caries and necrosis; says Weidmann, there is all that difference, which exists between ulcers and gangrene, or sphacelus, of the soft parts. In caries, the nutrition of the bone is only impaired, and an irregular action disunites the elements of the bony structure, which consequently sustains a loss of substance; but, every remaining part of it is yet alive. In necrosis, on the contrary, the vitality and nutritive functions cease altogether in a certain portion of the bone, the separation of which then becomes indispensable. (*De Necrosi Ossium*, p. 7.)

I have mentioned, that M. Louis confined the term necrosis to cases, in which the whole thickness of a bone perished; but, Weidmann judiciously criticises this limitation of the word, and maintains, that the nature of the disorder is the same, whether it affect a single scale, the whole, or a mere point, of the bone. He also objects to the definition of necrosis proposed by Chopart

(*Dissert. de Necrosi Ossium*, Paris 1766), and adopted by David. (*Obs. sur une Maladie connue sous le nom de Nécrose*, Paris 1782.) These two authors have defined necrosis to be a disorder, in which a portion of bone perishes, and turns dry, in order to be soon separated from the living parts, and replaced by a new bony substance, which is to perform its functions. But, as Weidmann observes, it may happen, that a piece of bone, which dies and separates, may not be replaced by any new formation of bone, though the disease is of the same character, and merely varies in some modifications. He therefore argues, and every rational surgeon will agree with him, that a true necrosis must always be said to exist, whenever a dead portion of bone has either separated, or is about to separate. "*Vera demum necrosis semper est, si aliquod ossis ramentum, in quo vis vitæ extincta est, abcessit, vel proxime abcessurum, est.*" (P. 7.)

The tibia, femur, lower jaw, clavicle, humerus, fibula, radius, and ulna, are the bones most frequently affected with necrosis. Excepting the lower jaw and scapula, the process of regeneration has only been noticed, in the cylindrical bones. From 12 to 18 years of age, is the time of life, most subject to necrosis. The necrosis of the lower jaw, however, seldom occurs before the age of 30. In some persons, two bones are affected at once, owing to constitutional causes.

No climate, age, sex, mode of life, nor condition, (says Weidmann) is exempt from the disorder. Childhood and puberty, however, are the periods most liable to it. The same thing may be said of persons, who labour hard, and are much exposed to external injuries. Every bone of the human body is subject to necrosis; but, those which are superficial, and enter into the formation of the extremities, are more frequently affected, than others whose situation is deeper. Necrosis less commonly attacks the spongy substance of the bones, because this being indued with a higher degree of vascularity and life, suppuration is most apt to occur. Necrosis, on the contrary, is oftener seen in the compact substance, where the vital principle is less energetic, and more readily extinguished. Lastly, the disorder may affect the long bones, or the broad; the large or small; and even those of the very least size; since it is well known, that the ossicula of the ear may be destroyed by necrosis, and separate. I have seen this happen in two instances, and the fact is recorded by several writers. (See *Astruc de Morbis Veneris*, lib. 4. cap. 1. *Henri, Journal de Médecine*, Tom. 15, p. 363.)

Though necrosis mostly attacks the cylindrical bones, the flat ones are not exempt from the disease. Pott makes mention of a parietal bone, the whole of which

was detached, and of an os frontis, the greatest part of which came away. In a thesis on necrosis, in 1776, *aux écoles de chirurgie*, may be found the case of a young man, a very large part of whose scapula perished and separated. Chopart, who relates the case, mentions, that he saw the patient quite recovered, and felt a new triangular moveable bone, firmly supporting the clavicle, but, smaller and flatter, than natural, and without any spinous process. The same has happened to the lower jaw, as may be seen by referring to the *Ephemerides Germaniae*, and *Mem. de l'Acad. de Chirurgie*. In the fifth volume of the latter work, is an account of a woman, who applied to be relieved of some venereal complaints. From the beginning of the treatment, the bone was discovered to be loose just under the gums, and seemed, shortly afterwards, to move backwards and forwards with a tooth. M. Guernery took hold of the tooth with a key-instrument, and found it firmly inserted in the moveable piece of the jaw; he made with caution the necessary manœuvres for extracting the portion of bone; but was greatly surprised on finding what an extensive part yielded to his very moderate efforts. It was the whole of the lower jaw, above its right angle, from its division into the coronoid and condyloid processes to the space between the first and second of the front grinders of the left side. On the right, there only remained the condyle in the articular cavity of the temporal bone. This destruction left a considerable empty space, from which great deformity was apprehended, in consequence of the unsupported soft parts falling down. The woman, however, got well in two months, and had the most perfect use of a new jaw. A similar fact is recorded in the *Journal de Medecine*, 1791.

When the body of a cylindrical bone, or the middle portion of a flat bone, is destroyed by necrosis, their extremities, which are of a cellular texture, continue unaffected, so that, for example, in the cylindrical bones, the articular ends are always formed of portions of the original bone, which are engrafted, as it were, on the new production. There are, however, a few bad cases, in which the necrosis does not altogether spare the heads of the bones, and the disease communicates with the joint. These examples are very uncommon, and are attended with considerable danger to the limb: indeed, they generally require amputation. (See *Boyer, Traité des Mal. Chir.* T. 3, p. 442.)

Besides the differences arising from the particular bones affected, necrosis also varies, according as the portion of bone attacked happens to be thin and of little extent, or large and of considerable thickness. The disease is *simple*, when it is con-

fined to one bone, and the patient is in other respects healthy; *compound*, when several different parts of the same bone, or several distinct bones, are affected at the same time; when the health is bad; and other parts of the body are also diseased. It should also be known, because the information is of practical importance in the treatment, that necrosis has three different stages, or periods. In the first, the bone affected perishes; in the second, the process of exfoliation, or separation of the dead bone from the living, is going on; and, in the third, the separation is completed. (See *Weidmann*, p. 8.)

The causes of necrosis are not essentially different from those, which produce ulcers and gangrene of the soft parts. As, however, the vitality of the bones is weaker, we may infer, that necrosis may be occasioned in them by causes, which are less numerous and intense, and such as would only give rise to suppuration in the soft parts. Every thing, whether in the periosteum, or the substance of the bone, itself, that tends to interrupt the nutrition of the bone, must be regarded as conducive to the origin of necrosis. It is to be observed, however, that when the mischief in the periosteum, medulla, or substance of the bone, is of trivial extent, the consequence is merely an abscess. Some of the causes of necrosis are *external*, while others are *internal*, or constitutional. Sometimes the life of the bone is instantaneously destroyed by them; but, in other instances, the bone is first stimulated and enlarged, so that its death is preceded by true inflammation.

The external causes, which injure the periosteum, and medullary structure, and thus produce necrosis, are wounds, contusions, pressure, fractures, comminutions, acrid substances, caustics, and extreme degrees of heat, or cold.

When the periosteum, in consequence of an external cause, inflames and sloughs, or is at once deprived of its vitality, as it may be by the action of caustic, fire, or intense cold, the vessels, which conveyed nourishment to the bone, are destroyed, and the death and exfoliation of the denuded portion of the bone are inevitable. But, if the detachment of the periosteum is of little extent, the patient young and healthy, and the treatment calculated to prevent inflammation, and preserve uninjured the vessels distributed to the bone, hopes may be entertained that no part of the bone will die, but that granulations will very soon arise from its surface, being adherent to it as the periosteum was, and that they will grow to and cicatrize with the surrounding parts. *Weidmann* has explained, that this fact of bones not always exfoliating when deprived of the periosteum, which is of great practical importance in the

treatment of wounds, was inculcated by Felix Würz, Cæsar Magatus, and Belloste, at a time when the contrary opinion prevailed. Weidmann also adverts to his own experience and to the experiments of Tenon, in further proof of the preceding fact. (*Mém. de l' Acad. des Sciences*, 1758, p. 372.)

On the other hand, when the detached piece of the periosteum is extensive; when the bone itself is contused; or when it has been long exposed to the air, the effect of which is to dry up the few vessels, which belong to it; when the inflammation is violent and extensive; when the patient is old, decrepid, or of bad constitution; and, more especially, when improper applications are used, as was almost always the case in former times; necrosis cannot be avoided.

An internal necrosis, affecting the spongy texture of bones, generally arises from constitutional causes, though, sometimes an external cause, which seems to affect only the surface of a bone, extends its action to the interior, so as to destroy the medullary membrane, and produce an internal necrosis.

In external injuries of the head, where the pericranium is lacerated, contused, or otherwise hurt, or where the outer table, or the diploe, of the skull, is injured, the inflammation frequently extends to the inner table, and the dura mater becomes detached. Hence, a collection of matter forms, which may occasion many bad symptoms, and even death itself; or, if the patient survive, an exfoliation of part of both tables of the skull is the consequence. (See *Pott's Chirurgical Works*. London, 1779, Vol. 1, p. 32.)

The same thing may occur in other bones, as well as those of the cranium. Bromfield had an opportunity of seeing a necrosis of the spongy substance of the upper and internal part of the tibia, brought on by the improper mode, in which an issue was dressed. In order to keep the peas from slipping out of their places, a compress with a shilling in it, and a tight bandage were applied; but, the part was attacked with excruciating pain, and the spongy texture of the tibia in the vicinity became affected with necrosis. (*Chirurgical Observations and Cases*, Vol. 2, p. 9.)

This circumstance, as Weidmann observes, ought not to surprise us: as numerous vessels quit the periosteum to descend into the substance of the bone, to ramify on the medullary cells themselves, and freely anastomose there, it cannot be difficult to conceive, how inflammation, which is at first confined to the outside of the bone, may (through the medium of the vessels, which serve as conductors to it) penetrate more deeply, and extend its ravages in every direction.

But, necrosis may proceed from another description of causes, which are of a constitutional nature. In fevers of bad

type, in the small pox, and in the measles, experience has fully proved, that the bones are sometimes attacked with necrosis. Scrofula, lues venerea, and the scurvy, are also diseases, which, according to the testimony of all surgical writers, frequently produce such mischief in the bones as terminates in necrosis. It is likewise well ascertained, that mercury, the judicious employment of which in venereal cases will prevent necrosis, or cure them when formed, may itself give rise to the disorder, especially in the lower jaw-bone. (See *Mém. de l' Acad. de Chir.* t. 5, p. 356. 4to.)

This happens either in consequence of mercury having been introduced too quickly into the system, or because the patient exposes himself to cold, or deviates in some other respect from a proper regimen. Certain necroses of the lower jaw, however, appear also to have been caused by blows, and the application of acrid substances to carious teeth. But, says Weidmann, "I feel it incumbent upon me particularly to declare, that the irrational treatment pursued by the ancient practitioners, who neither understood the nature of the bones, nor the differences of their diseases, and which treatment is too confidently adopted in our own days, had frequently the effect of killing these parts, by attacking with spirituous, acrid, or caustic remedies, or even with the knife, diseases, which required the mildest applications, and to be left in a great measure to nature. The old surgeons were afraid of laying on the exposed injured surface of a bone unctuous emollient dressings, and, yet, for what reason I know not, they subjected the part to the action of spirituous acrid drying applications. As for myself, I deem it proved by infallible and frequently repeated trials, not only that an exposed injured bone may be dressed with a mild ointment without any ill consequences, but even with the greatest advantage. Why, should that, which is beneficial to the soft parts, be so prejudicial to the bones? In ulcers of the soft parts, indeed, the employment of the remedy, which I recommend, is less important, because these parts are naturally humid, and there is no risk of their becoming dry. But, with regard to the bones, whose dry texture is only penetrated by few vessels, which may easily be destroyed if they be suffered to become quite dry, it is absolutely necessary to use an emollient ointment, as a dressing, well calculated to defend these vessels, which are the support of life, and preserve them from the bad effects of exposure to the air. Therefore, observes Weidmann, if a surgeon would avoid producing a necrosis himself, and not neglect any means, that tend to prevent such disorder, he should make it a rule never to apply any thing acrid to exposed bones, but, on

the contrary, to defend them with a dressing of some unirritating ointment." (*De Necrosi Ossium*, p. 11.)

It was formerly supposed, that purulent matter, collected near a bone, might in time become acrimonious, corrode the bone, and produce necrosis. Hence, it was a rule to open such an abscess as soon as its existence was known. But, Weidmann questions, whether there was any real necessity for this practice. No doubt, says he, the preceding erroneous opinion arose from the circumstance of the bones being often found bare, carious, or even affected with necrosis, when abscesses were near them; but, things happened thus, because the inflammation, which caused the suppuration, had also extended its effects to the periosteum and bone. He affirms, that he has witnessed ulcers, in which the surfaces of bones, bare and uncovered by the periosteum, lay bathed in pus for a very considerable time; yet, being dressed with a mild ointment, they continued entire, granulations grew from them, and cicatrization followed. He had also in his possession portions of bones affected with necrosis, which had lain for years in pus; still their surface was smooth, and presented no marks of erosion. If then these pieces of bone underwent no alteration, how much less likely to do so are bones, which are endued with life!

But, though Weidmann wisely rejects the doctrine of pus being capable of destroying the periosteum and bones by any corrosive qualities, he acknowledges his belief, that the matter of an abscess may by its quantity compress and inflame the adjacent parts, and occasion their removal by the absorbents. While the periosteum intervenes between an abscess and the bone, he does not see how the latter can be hurt by the pus; but, when the abscess is copious and lodged between that membrane and the bone, the vessels passing from the former will be destroyed, and either caries, or necrosis ensue.

The inflammation, arising from the causes which excite necrosis, may be either *acute*, or *chronic*. It is *chronic*, when it begins and passes through its different stages slowly, and when the mildness of the symptoms may lead us to mistake the nature of the case. This sort of inflammation chiefly happens in debilitated constitutions, in which the necrosis only affects the external part of a bone, and originates from some chronic cause, such as scrofula, lues venerea, and the scurvy. But, when necrosis attacks the interior, and the disease occurs in a strong, irritable, plethoric subject, inflammation is immediately kindled, attended with the most acute symptoms, severe pain, considerable fever, restlessness, delirium, &c. Chronic inflammation is more supportable; but its duration is longer:

acute inflammation is more afflicting, but sooner comes to a crisis.

The part, in which a necrosis is situated, is affected with swelling. What has been observed, respecting the inflammation, is also applicable to this tumour, which most frequently forms gradually, but sometimes with great rapidity. In the first case, the accompanying pain is dull and inconsiderable; in the second, it is violent. The swelling has not, like that of abscesses, an elevated apex. On the contrary, it is so widely diffused, that the limits, which circumscribe it, can hardly be distinguished.

This diffusion of the swelling is the greater, in proportion as the diseased bone is more deeply buried in soft parts: it may extend over the whole morbid bone, or even over the whole limb.

The swelling comes on at the very beginning of the disorder, and continues to increase, until the matter which it contains finds its way out, when the evacuation is followed by a partial subsidence of the tumour. The swelling is sometimes also combined with oedema, especially in persons, whose constitutions have been impaired by the severity of the disease, the violence of the sufferings, and the long and profuse discharge.

When the inflammation is acute, purulent matter of good quality soon collects in the vicinity of the necrosis. In the contrary case, the pus forms slowly, and is thinner and less healthy.

The abscess, which accompanies a necrosis, naturally soon bursts when it arises from intense inflammation, and is situated near the skin, which is itself inflamed. But, when the bone is surrounded by a great thickness of soft parts, and the inflammation is chronic, the quantity of matter daily increases, the cavity, which it occupies, becomes larger and larger, and considerable pressure is made by the abscess on every side. The bones and tendons resist for a long while the progress of the matter; but, the cellular substance yields, and different sinuses form, which sometimes run to a vast distance from the main collection of matter, especially, when the abscess lies under an aponeurosis.

It was supposed a few years ago, that, in cases of necrosis, the matter was invariably sanious, acrid, and fetid. But, the celebrated Weidmann exposed the error of this opinion. He had often seen abscesses and ulcers, arising from necrosis, discharge a whitish, inodorous, thick pus, absolutely devoid of any bad quality whatsoever. He had particularly seen this happen in patients, whose necroses proceeded from an external cause, or an internal one of a slight nature, and whose health was generally good. (*De Necrosi Ossium*, p. 16.) If, says the same excellent writer, we some-

times find in practice the suppuration dark and fetid, we must not ascribe it to the affection of the bone; but to the weakness and bad state of the patient's health. Under the same circumstances, common sores of the soft parts would also emit a discharge of bad quality.

After the ulcerated openings have emitted for some time a profuse discharge, the sinuses, if considerable, receive the appellation of fistulæ, on account of their edges putting on a callous appearance, throwing out fungous granulations, and there being impediments to cicatrization. These impediments are caused by the dead portions of bone, which, whether loose, or adherent, act as extraneous bodies in hindering the sores from healing. In some instances, also, the ulcers will not heal, though the dead bone has come away, because they run to a great depth, and such a quantity of pus is secreted from every point of their surface, as prevents all contact, and the adhesions, which would result from it.

The fistulæ vary in number; but, they are fewer in proportion as the disease is slighter. In an extensive necrosis, several of these openings are seen, either near together, or separated by considerable spaces; and, when the necrosis affects every side of the bone, the fistulæ in the integuments occur on every side of the limb.

Besides the inflammatory fever, which attends the beginning of every severe case of necrosis, which is sometimes accompanied with exceedingly violent symptoms, and which usually abates when the matter is formed, the patient is subject to another fever of a slow hectic type. This takes place in the decline of the disease, is the effect of the long continued profuse suppuration, gradually reduces the patient, and at length brings him to the grave, unless the timely removal of the sequestrum be effected either by nature, or art.

Let us next endeavour to trace the signs, by which we may not only ascertain the presence of the disease, but its modifications.

In the first place, we should make ourselves acquainted with every thing, which may have predisposed to the disorder; as, for instance, what accidental circumstances have occurred, and what symptoms followed them. We should also enquire into any previous treatment, which may have been adopted; for, as Weidmann truly remarks, injudicious remedies have caused many a necrosis, that would not have occurred at all, if the case had been properly treated, or confided to nature.

The kind of inflammation, with which the disease commences, may afford grounds for suspecting that necrosis will happen: it is generally slow and deeply

seated, passing through its stages tardily, and the attendant symptoms are severe. The skin retains its natural colour a long while; but, at length, exhibits a reddish, or livid discoloration. The matter does not reach the skin, till a considerable time has elapsed, and when the abscess bursts, the inflammatory symptoms are still slow in subsiding. When the inflammation is acute, the patient suffers intolerable pain a long time.

There are also other symptoms of a necrosis; viz. the swelling, which accompanies the inflammation, is situated upon a bone, or rather the bone is included in the tumour; the swelling is at the same time very diffused; and the suppuration lies deeply, and can only be felt in an obscure way.

The ulcers, beneath which a necrosis is situated, discharge a large quantity of matter, and their edges are bent inward. The granulations are either yellowish and pale, or else of an intense red colour; and they are also irregular, and generally not very tender, though sometimes extremely painful, and on being slightly touched, they bleed.

It has been already noticed, that, some years ago, the discharge from the sores, which attend necrosis, was described as being always thin, fetid, and sanious; and such qualities of the matter were regarded as a symptom of the disease of the bone. But, that excellent practical writer Weidmann has well explained, that it is a symptom, undeserving of confidence. In cases of necrosis the pus is often thick, white, and inodorous; while other ulcers, unattended with diseased bone, sometimes discharge thin, fetid matter. Weidmann, at the same time does not mean to assert, that, in cases of necrosis, the sores never emit unhealthy pus; but, he firmly believes, that such discharge is not always the result of a disease of the bone. As far as he could judge, the suppuration from ulcers, situated over diseased bones, continues white and laudable, as long as the patient's general health is good; but, that it deviates from these properties, in proportion as the health becomes impaired.

Neither is the black colour, imparted to the dressings of ulcers, a circumstance, which necessarily indicates the existence of necrosis; for, it may occur, when the bone is sound, and may not happen, when the bone is affected.

None of the preceding symptoms convey such information, as leaves no doubt of the positive existence of necrosis. The touch is the only thing, which can give us this knowledge, when the bone is not too deeply situated, and the sinuses not tortuous, nor obstructed with fungous growths.

When the openings of the ulcers are

considerable, the finger may be introduced. If, in this way, the bone can be felt to be extensively uncovered by the periosteum, the surgeon may conclude, that all such portion of the bone has perished. He may be still more certain of the fact, when he finds the edges of the denuded bone unequal and rough.

The examinations, made directly with the finger, give the most correct and exact information of the state of the bone; but, the orifices of the sores are sometimes so small, that the finger cannot be introduced, without causing great pain. A probe must then be used for the purpose of ascertaining the extent of the denudation of the bone; whether its edges are rough; whether the dead portion is loose, and likely to separate soon.

Sometimes, the dead fragment of bone protrudes from the ulcer, or is visible on separating its edges. When it is black, there cannot be a doubt of its being actually dead; but, on the other hand, when its whiteness is increased, the diagnosis is difficult, because bones being naturally white, much experience is necessary to be able to judge whether they are so in excess.

It merits attention, also, that the black colour of the bone is not owing to the necrosis itself, but seems rather to depend upon the fragment having been exposed to the air. In fact, dead pieces of bone with which the air comes into contact, turn black, while those, which are covered with matter, retain their whiteness. The cylindrical portion of a humerus, which was almost totally affected with necrosis, was universally black at the part, which protruded through the flesh; but the rest, which lay under the integuments, remained white. (*Weidmann de Necrosi Ossium*, p. 19, et Tab. 9. fig. 1.)

When the early symptoms of the disease are mild, the surgeon may infer, that it is only a superficial portion of the bone, which is about to be separated. But, this judgment will be more certain, if confirmed by examination with the finger, or probe; or if the swelling, which occurred in the beginning, has not spread beyond the affected point, and if the pain affects only the outer part of the bone. In this sort of case, there is also great probability, that the dead bone will be separated within a moderate time.

It is also of importance to ascertain the existence of an internal necrosis, and to learn, whether it is situated in the spongy substance, or in the internal parietes of the canal of the bone; whether it affects only a part, or extends to the whole body of the bone. When there is an internal necrosis, says Weidmann, the disease is generally more aggravated, and of longer duration; and, in the first stage, the pa-

tient is affected with severe symptoms, intolerable pain, loss of rest, ardent fever, profuse perspirations, and such disorder of the system, as may prove fatal, unless the patient be young and strong. The hard swelling, which was observable at the commencement of the disease, increases but slowly, and extends very gradually over the circumference of the limb, while the skin yet remains free from redness and tension. *If the part be somewhat roughly handled, the pain, which is fixed in the bone, is not rendered more acute, as would happen, were the case an external inflammation.* In this suffering condition, the patient continues a good while, before the formation of matter brings a degree of relief. When the matter is formed, it spreads through the adjacent cellular substance, amongst the muscles and other parts, and the abscess generally bursts, after a considerable time, by several openings, very distant from the main collection of matter, and also remote from each other, sometimes in diametrically opposite situations. The evacuation of the matter, however, does not produce any material subsidence of the swelling. The pus is of good quality, and issues in large quantities from the ulcerated apertures, *the quantity, however, not being increased when pressure is made.* If some of the openings heal, others are formed; but, in general, their edges become callous, and they lose all disposition to cicatrize. When the case presents the foregoing circumstances, and the weakened limb can neither bear the action of the muscles, nor the weight of the body, and by either of these causes, its shape becomes altered, the surgeon may conclude, that the disease is an internal necrosis. But, in order to avoid mistake, he should introduce into the sinuses, a probe, which, passing through the openings in the subjacent bone, will touch the dead piece, which it contains, and which will sometimes be even distinguished to be loose and moveable. *The extent of the sequestrum must be judged of, by the extent of the swelling, and the distances between the apertures in the bony shell, which includes the sequestrum.*

The surgeon should also endeavour to ascertain with the probe, whether there is only a single sequestrum, or several. When there are several, they may be felt with the probe in different places, down to which this instrument is passed, and the removal of one, or two of the fragments, is not followed by a cure. It ought to be remembered, however, that the same fragment may be touched by the probe in several different places, when it is very extensive. If there are several dead pieces of bone, situated at a distance from each other, each of them is generally accompanied with a distinct swelling, and sinuses. Frequently, these fragments are so concealed, that they

cannot be felt with a probe; but, their existence may then be suspected from the ulcers not healing, which can be ascribed to nothing else.

It is also necessary to distinguish with the greatest attention the different stages of the disease. The *first stage* may be considered as existing, when the attack is yet recent, and the inflammation and its concomitant symptoms, the pain, swelling, and symptomatic fever, prevail in a high degree, and when no suppuration has taken place, or at least no discharge of matter. The *second period*, in which the dead bone is undergoing the process of separation, is indicated by a diminution of the inflammation, a partial subsidence of the swelling, and the discharge of purulent matter. When a probe is passed into the ulcers, the bone is felt bare, and dry, and, towards the limits of the swelling, it is rough, where as will be afterwards noticed an excavation is formed. Every part of the bone, however, which is to be detached, still continues adherent to the rest of the living bone. At length, the surgeon knows, that the disease has reached its *last stage*, or that, in which the dead portion of bone, is entirely separated, when sufficient time for the completion of this separation has expired, and when the dead bone can be distinguished with the finger, probe, or even the eye, to be loose and free from all connexions.

Although a necrosis must generally be classed with diseases which are serious and of long duration; yet, the character of the disorder is not essentially bad, since it is often cured by nature, or with the assistance of surgery. Confident hopes of a cure may be entertained, when the necrosis is confined to the external part of a bone; when it is simple and of moderate extent; when it is not situated in a bone, destined for important uses, or near any viscus, or organ, that may be injured by it; and when it proceeds from an external cause, and the general health is good. On the contrary, the cure is difficult, and the prognosis doubtful, when the disease is extensive, and complicated with other affections, either of the same, or different bones; when it attacks bones, which are of high importance on account of their functions, or situation; when it is situated in the interior of a bone, and affects several parts of it; when it arises from an internal cause, for which there is no certain and quick-acting specific; when the patient is weakened by age, or disease; and, especially, when the sinuses extend into the neighbouring articulations. (*Weidmann de Necrosi Ossium*, p. 22.)

The process of cure is said to take place with more celerity in the lower jaw, than any other bone, and may be completed in three months. Mr. Russell has

never known a necrosis of the tibia get well in less than a year; but, in general, nearly two years elapse first; sometimes, the cure is protracted to a much greater length of time.

Necrosis of the lower jaw and clavicle never proves fatal: that of the lower extremities, which is the worst case, does so very seldom, and only, from the violence of the first inflammatory symptoms, which rapidly bring on a hectic fever, which proves incurable, unless its local cause be removed by a timely amputation. When the violence of the first stage, however, has abated, the irritation ceases, and the hectic symptoms, if there are any, are generally moderate. Nor is this state of tranquillity disturbed, till the sequestrum, in making its way outward, again produces irritation. At this second period of urgency, extensive inflammation may originate, ulcerations spread all over the surface of the limb, assume an unhealthy appearance, violent fever succeed, and the patient either perish, or sink into a state, in which he must consent to amputation, as the only means of saving his life. This is the last crisis of eminent danger; but, in general it is less perilous, than when the inflammation comes on in the incipient stage of necrosis. (*Russell*.)

In the treatment of necrosis, the first grand object of the surgeon should be to aid nature in her endeavours to effect a cure, and not to disturb her operations by any superfluous, or unseasonable interference. The second should be to assist her sometimes by the boldest proceedings, when she loses her way, and cannot by herself accomplish the end.

But, in order not to attempt any thing wrong, the surgeon must understand correctly what nature does in this disease, what it is in her power to perform; what she either cannot accomplish at all, or not with any degree of certainty; and lastly the circumstances, in which she may err, and endanger the patient's life.

When a portion of bone dies, nature uses all her endeavours to bring about its separation from the part of the bone, which still remains alive. Surgeons have denominated this process, *exfoliation*, (*See this word*), which resembles the separation, that occurs between parts affected with gangrene and sphacelus, and the living flesh. An exfoliation of bone, however, happens much more slowly, than the separation of a slough of the soft parts. Neither are all exfoliations completed at a regular period; for, they proceed most quickly during youth, when the constitution is usually more full of energy, the bones more vascular, and less replete with solid inorganic earthy matter. On the other hand, the process is slower, in old, debilitated subjects, whose vitality is less

active. A thin, small scale of bone separates sooner, than a large thick portion; and the most tedious exfoliation is that of a thick bone, from which a portion, including its entire diameter, is coming away. The separation of a necrosis takes place more expeditiously in bones of a light texture, than in those of a solid structure; and sooner, in the less compact parts of bones, such as the epiphyses and spongy substance, than in those of greater density.

When a necrosis has originated from the scurvy, syphilis, &c. and appropriate remedies are not administered, nature cannot effectually accomplish the process, by which the dead bone is separated; the case becomes worse; and life endangered.

The separation happens precisely at the different points where the living and dead parts of the bone come into contact; and it is obvious, that the particles of the dead bone, which are at a distance from the part, that retains its vitality, cannot be acted upon by it.

A variety of opinions have been entertained, concerning the means employed by nature in effecting this separation. Hippocrates believed, that the dead part was pushed away by a fleshy substance, which grew underneath it. (*De Cap. vuln. Cap. xxiv.*) Ludwig, Aitken, Bonn, and many others, adopted the same idea. (See *Adversaria Med. Pract. Vol. 3, p. 63*; *Systematic Elements of the Theory and Practice in Surgery, p. 287*; *Thesaur. Oss. Morb. p. 1.*)

Van Swieten conceived, that the dead part was forced away by the incessant beating of the arteries. (*Comment. in Aphor. Boerrhavi, § 252.*) M. Fabre ascribed the separation to the extension and expansion of the vessels. (*Mém. de l'Acad. de Chir. Tom. 4, p. 91.*) Others supposed that the exfoliating piece of bone became loosened partly by the suppuration, and partly by the rising of the new granulations. (See *B. Bell on Ulcers.*)

As Weidmann observes, there is unquestionably a reddish fleshy substance formed between the dead and living bone, and which Celsus has noticed under the appellation of caruncula. (*De Medicina, lib. 8. cap. 3.*) But, it would be erroneous to refer the expulsion of the dead portion of bone to it, since it can never be produced, before a change has taken place in the structure of bone, there being in fact no space for it to grow in; and hence, it is never seen before the disunion of the parts has considerably advanced. There must consequently be some other power, which destroys the cohesion between the dead and living bone, and produces the groove, or interspace, in which the soft granulations arise. Besides, amongst other facts proving the falsity of the idea, that the granu-

lations push off the dead bone, Weidmann particularly adverts to the occasional exfoliations of the whole circumference of a cylindrical bone. Here, if the granulations had the power of causing a disunion on one side, they could not have the same effect on the opposite one; but, would tend to make the contact more intimate.

The separation also cannot be made by the pulsation of the small arteries, nor by the weak expansive motion of the vessels of the bone. Weidmann knows not what motives have induced certain writers to impute the effect to suppuration, and observes, that, as the doctrine is not founded upon reasoning, it is superfluous to offer any arguments against it. If the least attention be paid to what nature really tries and accomplishes in this operation, nothing will be more manifest, than that it is completed in a very different manner. Swelling first affects the periosteum and bone, which by degrees softens. (*Vid. Troja passim. Bonn. Thesaur. Oss. Morbos, p. 122, and Weidmann de Necrosi Ossium, Tab. 4. Fig. 1 and 3.*) At the margins of the necrosis, the bony surfaces, which were smooth, become rough, and irregular. A fissure is there produced, which extends in every direction under the piece of bone, that is about to be detached. The bony texture is also daily rendered less solid, so that the number of adhesions between the dead and living parts diminish, and in the end are totally destroyed. Weidmann then explains, that the true mode by which the separation is effected, consists in the absorption of the particles, situated betwixt the living and dead parts of the bone, in such a way, however, that the first loses a great deal of its substance; the last, scarcely any thing. (*P. 25.*) After the dead bone has come away, the swelling of the periosteum subsides, and the living bone recovers its original hardness and solidity. (*Troja, p. 67.*)

For a further account of the process, by which dead portions of bone are separated from the living, see *Exfoliation*.

When dead portions of bone are separated and loose, they still lodge in the cavities of the ulcers, and, like all other extraneous bodies, occasion irritation of the soft parts, and keep up a discharge of matter. Sometimes, however, nature of herself succeeds in expelling them. This happens in cases, where the size and shape of the ulcer are calculated to facilitate the issue of the dead bone, which does not lie too deeply, and is propelled outward by its own weight. In necroses of trivial size, indeed, it is asserted, that the small fragments of bone may be dissolved in the pus, and come away with it; (*David; Bousselin, Hist. de la Société Royale de Médecine, Tom. 4, p. 308*; *Weidmann de Necrosi Ossium, p. 26.*) but, such an event can never be expected

when the dead portion of bone is at all extensive.

The last thing, which nature does, is to restore the loss of substance which the bone has suffered. Although this operation is so extraordinary, and wonderful, that one might be disposed to doubt its reality, numerous examples, recorded in the annals of surgery, prove not only its possibility, but, also, its frequency.

In works, referred to at the conclusion of this article, the following authors speak of the regeneration of a part, or the whole of the lower jaw-bone: viz. Bonetus, Bayer, Guernery, Belmain, Acrel, Van Wy, Trioen, Bonn, Reiplein, Desault, Henkel, and Dussaussoir. A student shewed Weidmann a lower jaw-bone, which had been thus regenerated, and taken from the body of a man, whom the latter distinguished writer had been well acquainted with. The bone could not be freely depressed; but, yet, it performed its functions tolerably well.

Moreau saw a case, in which the clavicle was regenerated, and the new bone was presented by Dangerville, after the patient's decease, to the Academy of Surgery at Paris. (*De Necrosi Ossium Theses, Præs. F. Chopart, resp. P. G. Robert, Parisiis, 1776.*)

Chopart had an opportunity of witnessing the death and reproduction of a scapula.

Weidmann saw an instance, in which nearly the whole cylindrical shaft of the humerus perished, and was afterwards regenerated; a phenomenon, that had been observed at earlier periods by Job of Mekren, Cajetano Taconi, E. Blancard, Duhamel, David, Acrel, Bœhmer, Cheselden, and Vigaroux, whose respective works are cited at the end of this article.

Morand, Cheselden, and Bromfield published engravings, representing a reproduction of the upper part of the humerus, where the old dead bone was included in a sort of bony tube.

Regenerations of the ulna have been observed by Ruysch, Duverney, and Fowles. (See *Thesaur. X. No. 176; Traité des Mal. des Os. Paris, 1751; and Phil. Trans. No. 312.*)

A similar reproduction of the lower ends of the radius and ulna was witnessed by Acrel. (*Chirurgische Vorfälle von Murray, Vol. 1, p. 194.*)

Similar reproductions of the thigh-bone are recorded by Wedel, Battus, Koschius, Hofmann, Scultetus, Diemberbroeck, Wright, Fabricius Hildanus, Raw, Dobyns, Mackenzie, Ludwig, David, Rousseau, Larrey, Hutchison, &c. in publications specified at the conclusion of this subject.

The following case of necrosis of the thigh-bone is related by Dr. Mackenzie. —William Baxter, a boy thirteen years

old, received a blow on his thigh at school, of which he at first hardly complained; but, in a few months, he began to have pain in the thigh, which inflamed, swelled, and appeared to have matter in it. The parents being poor, no surgeon was called, and the boy was allowed to linger for a great while. At length the matter made its way through the skin, by a small opening, on the interior part of the thigh, about three inches above the knee, and a thin sanies continued to be discharged for eighteen, or twenty months. At length, the hole in the skin enlarged, and the point of a bone began to protrude, and give a good deal of pain, when the clothes rubbed against it. After suffering in this manner for two years and a half, the boy, as he lay in bed one morning, felt the bone looser, and projecting more, than ordinary. He gave it a strong pull, and brought the piece away entirely, which proved to be seven inches and a half of the thigh-bone. A good deal of bleeding followed; but, the wound soon healed, and he has never since found the least inconvenience. Dr. Mackenzie, hearing of this singular case, sent for the boy, carefully examined his thigh, and found it as firm as the other. The only difference was, that it was somewhat thicker, and a little more curved. The muscles retained their natural softness, and looseness on the bone. The detached piece of bone was a portion of its whole circumference. (See *Med. Obs. and Inquiries, Vol. 2.*)

We may infer, that the occurrence is more frequent in the tibia, than any other bone, from the accumulated facts, mentioned by Albucasis, La Marche, Muralto, De la Motte, Ellinchuys, Ruysch, Tacconi, Laing, Johnson, Hunter, David, Boehmer, Sigwart, Th. Bartholine, Hofmann, Saviard, Le Dran, Duverney, Trioen, Gunther, Ludwig, Michael, Bousselin, Weidmann, Russell, Whately, Desault, &c. See the works referred to at the end.

Dr. Hunter mentions a tibia, which was sent to him by a Mr. Inett, after amputation. On examination, the case at first sight seemed to be a swelling of the whole bone, with a loose internal exfoliation. However, it proved to be a remarkable instance of the separation of the greatest part of the original bone whose place was supplied by a callus. The external surface of the inclosed loose piece of bone was smooth. A small part of the surrounding bony substance being removed, the contained piece was taken out, and found to be the whole body of the tibia. It had separated from the epiphysis at each extremity. The middle part of the bone had perished, consequently, had lost its connexion with the periosteum, and was gradually thrown off from the living parts of the bone at each end. A callus extended

from end to end, united the two extremities of the original tibia, preserved the length, and gave firmness and inflexibility to the part. The exfoliation was so encompassed by the new bony case, that, though quite loose, it could not be thrown out. (*Med. Obs. and Enq. Vol. 2.*)

Weidmann saw a shoe-maker, who, after much suffering, extracted himself the greatest part of the diaphysis of the tibia; yet, the loss was so well repaired, that the man could walk afterwards nearly as ably as ever. (*De Necrosi Ossium, p. 29.*)

"We are not to imagine, (says Weidmann,) that these regenerations happen by chance: experiments made upon living animals by Troja, Blumenbach, Koehler, Desault, and myself, prove, that they invariably follow certain laws."

In fact, whenever the medullary structure of the long bones of pigeons, or dogs, is destroyed, these bones become affected with necrosis, and are afterwards reproduced to the full extent of their destruction.

The observations and experiments, cited by Weidmann, also prove, that it is the long bones which are usually reproduced; though the flat ones are not entirely destitute of the power of regeneration, since experience fully evinces, that, when a portion of the skull is removed, either by a wound, by disease, or by the trepan, nature always endeavours to cover the deficiency, the edges of the aperture extending themselves by means of a bony substance, furnished by the periosteum, the dura mater, and cranium itself. (*Tenon Mém. de l'Acad. des Sciences, 1758, p. 412, 413, 415, 416, 418.*) But, still the reproduction is imperfect, as a space unfilled up is always left, even when the bone has lost only a small piece, like what is taken out by the trephine; and when the destruction of the cranium is very extensive, no reproduction at all happens. This fact is proved by examples mentioned by Saviard, Pott, Sabatier, &c.

When, in a case of necrosis, says Weidmann, a scale, or table of either a long, or flat bone, is separated, no regeneration follows, because the granulations, which rise up under the sequestrum, then serve as a periosteum, and as soon as the dead bone is removed, they become united to the adjacent parts.

It is likewise ascertained, that the power of reproduction in the bones is particularly active in the early periods of life, and in healthy subjects; and that it is languid and even annihilated in old persons, pregnant women, (*Bonns Thesaur. p. 174.*) and in venereal, cancerous, and ricketty patients. (*Callisen, Syst. Chir. Hodiernæ, Pars 1, page 636.*)

In order that a new bone may form, the periosteum and other membranes, con-

cerned in the nutrition of the original bone, must have been spared from destruction. In fact, continues Weidmann, we observe, that, in cases where the tube of a long bone has suffered necrosis, the bone is never reproduced, when the periosteum has been destroyed by inflammation, or other causes. Surgeons ought also to understand, that it is not always a reproduction which has happened, when a part of a bone perishes; not even when a tubular portion of a long bone dies, and is contained in the medullary canal. For, says Weidmann, if the innermost layers of a long bone perish, while those which compose, as it were, the bark, are preserved, the latter swell and soften, as if they were actually a new bone. Several round apertures are observable upon their surface, which serve for the transmission of vessels, and are larger than those, which perform this office in the natural state. There are likewise formed large openings, or fistulæ, which, as in a new bone, lead to the medullary canal. Here it would be erroneous to conclude, that a new bone has been produced, and a very little attention will discover, that all is limited to some changes in the external part of the bone, which the necrosis has not affected.

When, therefore, the interior of the canal of a long bone is destroyed by a necrosis, which does not extend to the external layers, the case is not a reproduction of the bone.

When, however, we find the tube of any long bone included in a sort of osseous shell, and the surface of this tube smooth, like that of a bone in the natural state, we may be certain, that it has been detached directly from the periosteum, and that the bony shell, which contains it, is a new production. On the contrary, if the surface of the dead tube is rough, we may infer, that the separation has taken place between the innermost layers of the bone, and those which are superficial, the latter composing now the osseous shell, in which the sequestrum is included. (*Weidmann De Necrosi Ossium, p. 31.*)

This last theory, concerning the production of the osseous shell in necroses of the long cylindrical bones, is adopted by Richerand as the true one, not only in the instances specified by Weidmann, but in every other example, where the old bone seems to be included in another which has the appearance of being a new production, and which was supposed by Troja, David, &c. to be formed by the vessels of the periosteum. (*See Nosographie Chir. T. 3, p. 158, 161, Edit. 4.*) Boyer does not espouse this theory exclusively; but represents the thing as sometimes happening. (*See Traité des Mal. Chir. T. 3, p. 426.*)

As far as the observations of Weidmann informed him, the short or cuboid bones de-

not appear to be capable of reproduction. (P. 31.) Duverney mentions an astragalus, which was destroyed by necrosis; but, does not state, that any substitute for it was afterwards formed. (*Traité des Maladies des Os*, p. 458.)

Weidmann also never witnessed a reproduction of the spongy substance, such as it was before its destruction, round the medulla. He always found the substituted matter dense and compact, at least, for some time after its formation.

It is now admitted, however, that, in process of time, the inner surface of the new bone becomes cellular, and is lined with a membrane containing medulla. The regeneration of the medulla was first observed by Koehler, and afterwards in an extensive series of experiments, which Professor Thomson made with Dr. Alexander M'Donald, and which were published in the latter gentleman's inaugural dissertation in 1799. (See *Thomson's Lectures on Inflammation*, p. 393.) Mr. Russell does not appear to adopt this opinion, concerning the regeneration of the medulla; for, he states, that, after the absorption, or removal of the sequestrum, the cavity of the new bone becomes filled up with granulations, which are at length converted into bony matter. Thus, he says, the new bone differs from the original one, in being solid, instead of hollow. Authorities, however, are decidedly against Mr. Russell on this point: in the 5th vol. of the *Mém. de l'Acad. de Chirurg.* is the history of a man, the whole of whose clavicle came away, without his being deprived of any of the motions of the arm. The death of this patient, which happened shortly afterwards, afforded an opportunity of examining how nature had repaired the loss. Another clavicle was found regenerated, which neither differed from the original one in length, or solidity; but, only in shape, being flatter, and not so round. It was connected with the acromion and sternum, just like the primitive bone.

The power, which thus reproduces bones, is only a modification of that, which unites fractures. Indeed, what consolidates broken bones, and is known by the name of *callus*, presents all the characters of new bone, begins and grows in the same way, and may be impeded and retarded in its formation by the same causes. (See *Callus and Fractures*, p. 405—408.) It is further highly probable, as Weidmann remarks, that the power, which effects the reproduction of bones, is the same as that, which, in the sound state, nourishes and supports these parts. But to what organ appertains the function of reproducing bones?

Many able men have ascribed the whole work to the periosteum. (C. Havers; Duhamel, *Mém. de l'Acad. de Sciences*, 1739, 1741, 1742, 1747. Fougereux, *Mém. sur les*

Os; Paris, 1760. Swencke, *Harlemer Abhandlungen* 1. th. p. 39. Bertin, *Ostéologie*. Marignies, *Abhandlung von der Natur und Erzeugung des Callus*, p. 199.)

Haller, (*Elem. Physiol.* T. 8, p. 352.) Callisen, (*Collect. Hafn.* T. 2, p. 187.) Tenon, (*Mém. de l'Acad. des Sciences*, 1758, p. 415.) Bordenave, (*Mém. sur les Os*, p. 227.) and many others, have seen a part of the new production spring up from the substance of the old bone; a thing, says Weidmann, which one is also led to believe by the fact, that, when the whole tube of a long bone is affected with necrosis, the epiphyses, which remain sound and untouched, unite and grow to the new tube, though no periosteum exists in the situation of the union.

Nor does Weidmann think, that the specimen of a fractured thigh, of which Blumenbach has published an engraving, proves the contrary. (*Geschichte und Beschreibung der Knochen*; Göttingen, 1786, tab. 1, fig. 1.) This preparation exhibits an union, which had taken place by means of a very broad osseous ring, encompassing the ends of the fracture, which lie far asunder. The event appears to Weidmann to have been the result of rachitis, or lues venerea, with which the young patient, according to Blumenbach himself, had been affected, and by which the nutrition of this bone had been disordered. For, says Weidmann, in other examples of united fractures, the ends of the bone are so connected together by the callus, that there does not exist a single point between them, where this substance is not effused, and the medullary canal itself is obstructed and filled with it.

That, however, the periosteum is frequently the organ of the reproduction of bones, is proved by the experiments of Troja, Blumenbach, Desault, and Koehler, since in these the bones were invariably regenerated, though there was nothing left of the old bone, that could furnish the new reproduction, except the periosteum.

If we examine the new bone, at the different periods of its developement, it appears in the earliest state in the form of a reddish fluid, as has been observed by Duhamel, Fougereux, Bordenave, Haller, Callisen, and others. If we also attend to the progressive changes, which this fluid undergoes, we cannot but believe, that, as in the embryo, an organic and fixed arrangement of parts takes place. Indeed, it would be erroneous to consider such fluid as destitute of organization and extravasated at random. Thin and little in quantity on its first appearance, its consistence and quantity afterwards gradually increase (*Troja*, p. 42—44,) so that what at first appeared like a liquid, soon becomes a gelatinous substance, in which are developed, especially at its inner surface

and towards its lower part, bony fibres, which incessantly become more and more numerous. These fibres in a short time form little layers and cells, and extend themselves every where, so that at length all which was fluid disappears, and the new bone is produced. While young, however, it is still spongy and reddish, (*Troja*, p. 44); but soon becomes denser, harder, and more solid, than that was for which it is a substitute, and it acquires the ordinary colour of the rest of the bones.

The external surface of the new bone, which, during the period of its formation, was irregular, and studded with several excrescences of various sizes, and pierced with apertures of different dimensions, becomes in the course of time smooth and regular, especially after the expulsion of the sequestrum.

The sides, or walls of the new bone, which at first were of considerable thickness, in time also grow thinner. (*Troja*, p. 21.) When the entire dead bony cylinder continues in its cavity, the new bone is neither shorter, nor longer, than the original. But, should one of the ends of the dead tube protrude from the cavity, while by the side of the affected bone, there is not another one capable of resisting the action of the muscles, the new bone will be shortened, and undergo some change in its shape and direction. Indeed, says Weidmann, the new bone, in its early state, from want of consistence, must yield to the efforts of the muscles.

Its shape is not exactly like that of the original bone: the sides are flatter; the usual angles, depressions, and eminences are not observable, and sometimes others are formed.

How admirable is the process, by which the muscles, detached from a bone affected with necrosis, have other insertions given to them, and are thus rendered capable of performing their functions! (*Troja*, p. 27.)

The periosteum, which swells as soon as the exfoliation of the old bone commences, shrinks, and is not at all thickened, when the exfoliation is finished. *Troja*, having destroyed the medullary structure of a long bone, found the periosteum swelled at the end of 36 hours; but he observed, that the whole of such swelling disappeared before the 25th day. (P. 43 and 67.)

The periosteum, which thus survives, adheres to the new bone, as it did to the old one: its vessels, which are now increased in diameter, and convey a larger quantity of blood, dive into large apertures in the regenerated bone, ramify every where in its substance, and nourish it.

Dr. Macartney's observations nearly agree with those of *Troja* and Weidmann, respecting the formation of the new bone by the periosteum, with this difference,

however, that he does not describe the original periosteum as becoming afterwards attached to the new bone, but as disappearing. Dr. Macartney remarks, "that the first and most important circumstance is the change, which takes place in the organization of the periosteum; this membrane acquires the highest degree of vascularity, becomes considerably thickened, soft, spongy, and loosely adherent to the bone. The cellular substance, also, which is immediately connected with the periosteum, suffers a similar alteration: it puts on the appearance of being inflamed, its vessels enlarge, lymph is shed into its interstices, and it becomes consolidated with the periosteum. These changes are preparatory to the absorption of the old bone, and the secretion of the new osseous matter, and even previous to the death of the bone, which is to be removed. In one instance, I found the periosteum vascular and pulpy, when the only affection was a small abscess of the medulla, the bone still retaining its connexion with the neighbouring parts, as it readily received injection. The newly organized periosteum, &c. separates entirely from the bone, after which it begins to remove the latter by absorption;" and, while this is going on, its inner surface becomes covered with little eminences, resembling granulations. "In proportion as the old bone is removed, new osseous matter is dispersed in the substance of the granulations, whilst they continue to grow upon the old bone, until the whole, or a part of it, is completely absorbed, according to the circumstances of the case. What remains of the investment, after the absorption of the old bone, and the formation of the osseous tube, which is to replace it, degenerates, loses its vascularity, and appears like a lacerated membrane. I have never had an opportunity of examining a limb, a sufficient time after the termination of the disease, to ascertain, whether the investment be at last totally absorbed, but, in some instances, I have seen very little remaining. During the progress of the disease, the thickened cellular substance, which surrounded the original periosteum, becomes gradually thinner; its vessels diminish, and it adheres strictly to the new-formed bone, to which it ultimately serves as a periosteum." Dr. Macartney states, that the anatomical preparations, which authenticate the above observations, are preserved at St. Bartholomew's Hospital. (See *Crowther on White Swelling*, p. 183, Edit. 2.)

Mr. Stanley, however, lately shewed in the same museum, a preparation, which tends to confirm the accuracy of *Troja's* account of the old periosteum becoming adherent to the new bone. In this example, the periosteum is perfectly continuous with that covering the epiphyses.

If this were not the fact, we should have to explain in what way the periosteum of the new bone is formed. We know that the vessels of the original periosteum enter the new bone, in order to complete its formation, and it seems more consonant with the uniform simplicity of nature's operations, to suppose that this connexion is kept up, than that the old periosteum should be totally removed, after the production of the new bone, and another membrane of the same kind be then generated.

An interesting example of necrosis of the thigh-bone, very lately published by Dr. Hutchison, tends also to prove, that the new osseous shell is commonly formed by the periosteum, as, in this case, the medullary bags, or cells, were found completely ossified, (*Practical Obs. in Surgery*, p. 135.) and could not therefore be supposed to be capable of the work. Amongst the moderns, also, Dr. M'Donald deserves to be mentioned as one of the most distinguished advocates for the truth of Troja's explanation of this subject. (See *M'Donald's Thesis de Necrosi ac Callo*; Edinburgh, 1799.) Another late writer has adduced many arguments to prove, that the pulpy mass, which extends from one epiphysis to the other, and is itself at last converted into bone, is formed quite independently of the original bone, or the periosteum. (See *Russell's Practical Essay on Necrosis*, p. 27, Edinb. 1795.) This account, however, is contrary to the observations of Troja, David, Weidmann, M'Donald, Macartney, and numerous accurate observers. Indeed, a modern author seems to think the periosteum so essential to ossification, or the production of a new bone, that he attempts to explain the cause of fractures of the patella not becoming united by a bony substance, by adverting to the deficiency of periosteum upon it; a circumstance, which he deems also a strong argument against Mr. Russell's doctrine. (See *Hutchison's Practical Observ. in Surgery*, p. 141—142.)

Professor Boyer does not refer all the work of reproducing bones exclusively to the periosteum in every instance. We have already noticed, that he joins Weidmann in believing, that what seems a new bone is sometimes only a separation and thickening of the external layers of the original bone, which have escaped destruction. He notices the modifications, to which the phenomena of necrosis are subject when the disorder affects the whole thickness, and the whole, or the greater part of the circumference of a long cylindrical bone. "When the periosteum is destroyed together with the bone, and the medullary membrane, which does the office of an internal periosteum, is preserved, Boyer represents the latter membrane as undergoing similar changes to those which we have mentioned as taking place, under

other circumstances, in the external periosteum, and he describes it as becoming the organ, by which the new bone is formed. (See *Traité des Maladies Chir. T. 3*, p. 432.) But, when the whole thickness and circumference of a long bone are destroyed, together with the medullary membrane, while the periosteum survives, Boyer agrees with Troja, &c. in believing the latter membrane to be the means by which the new bone is generated.

The internal surface of the new bone is lined by a new membrane, which serves as a periosteum, and is at first hardly distinguishable. (*Troja*, p. 56.) In the early state, it is soft and pulpy; (*ibid.* p. 22.) but, by degrees, it grows thicker and firmer, and is at length converted into a true membrane, which sends a great number of vessels into the substance of the bone. When this membrane is torn off, the surface, which it covered, is found somewhat smooth, the edges of the bony layers, and projections of the fibres being blunt and rounded.

The cavity of the new bone includes, and almost entirely conceals the dead fragments. Sometimes, however, the new bone forms a sort of bridge over the sequestrum, in such a manner, that the cavity is open above and below, in both which situations the sequestrum can be felt. (*Hunter, in Med. Obs. and Inquiries*, Vol. 2, p. 418.)

Sometimes, it is only a narrow cross piece, which forms the bridge retaining the sequestrum. (*Weidmann, vid. Tab. 5, Fig. 1, a.*)

The new bone may also have an opening in it, out of which the dead portion protrudes. (*Ibid.* p. 35.)

Sometimes the cavity of the new bone is single; while, in other instances, there are several successive cavities in the direction of the length of the bone, with transverse interspaces between them; or else the cavities are situated laterally with respect to each other, and divided by partitions. (*Weidmann, Tab. 7, Fig. 2.*)

These cavities are proportioned in size and shape to the fragments of dead bone, which lodge in them. It occasionally happens, that they open into some neighbouring joint, and bring on suppuration there: a very unfavourable complication. (*Ibid.* p. 34 and *Tab. 6, Fig. 3*; also, *Boyer Traité des Mal. Chir. Tom. 3*, p. 435.)

Let us next follow Weidmann, and take notice of the holes, by which the cavities, including the dead pieces of bone, open externally, which Troja denominated the large foramina, and which the preceding excellent writer preferred calling the *cloacæ*, because they serve to convey outward the matter and any separated pieces of bone. In the beginning of the disorder, they are not observable, a certain space of time appearing to be requisite for their formation,

They are noticed in long cylindrical bones, whether original, or of new production, whose cavities contain dead fragments.

These openings vary in number: when the sequestrum is small, only one is found; but, when the piece of dead bone is extensive, there may be two, three, or four. Weidmann never saw more than five. But, Troja met with eight. (P. 58.) Weidmann possessed a small portion of the diploe of the os innominatum, which was affected with necrosis, and contained in a bony cavity, that had no external opening whatever.

When there are several distinct cavities in the same bone, containing dead fragments, each cavity has at least one external opening.

These *cloacæ*, or apertures, are commonly situated at the lower and lateral parts of the cavities; pass obliquely outwards; and communicate with fistulous ulcers, which open on the surface of the skin. (David, p. 186.) Some of the *cloacæ*, however, form at the middle, or, (what is exceedingly rare) at the upper part of the cavities, and proceeding outward, without any oblique track, go to the front, back, or lateral parts of the limb.

They are of a round, or oval shape, or nearly so. Their usual size is such, that it will just admit a quill, and they vary very little from this dimension.

They terminate internally by converging approaching edges, in the manner of a funnel; while, on the contrary, the margins of their outer extremity expand. The canal, between these two orifices, is sometimes long, sometimes short, and in certain cases of no extent at all.

Different opinions have been broached, respecting the causes, which produce the apertures in the new bone, termed by Weidmann the *cloacæ*.

M. David says, that the pus, collecting in an early stage of the disease between the bone and periosteum, distends and corrodes this membrane, and that the openings, which form in it, become afterwards a cause of fistulæ in the new bone. (P. 186.) But, it is observed by Weidmann, that this explanation is inadmissible, since the existence of the collection of pus, mentioned by M. David, is not proved by observation: in fact, it was never met with by Troja, Blumenbach, Desault, Koehler, and many others, in repeated experiments made on the subject. (Troja, p. 56 and 66; Weidmann, p. 36.)

Koehler thought he had seen the new bone itself destroyed by the pus, and *cloacæ* thus produced. (P. 68—72.)

Weidmann, however, deems this opinion quite as improbable as the preceding, for the fact of the surface of these bony apertures being always smooth, always formed in one manner, and constantly lined by the

periosteum, decidedly proves, that they cannot arise from erosion.

Troja, in his third experiment upon the regeneration of bones, remarked, that 42 hours after the destruction of the medulla, there took place, between the bone and the periosteum, an effusion of lymph, which was at first thin and little in quantity, but afterwards became thicker. He noticed, in the midst of this gelatinous substance, some small spaces, where it was deficient, and which had, instead of it, a subtile, whitish, dry incrustation, which though tolerably adherent, could be rubbed off. These small spaces, according to Troja, produce the apertures, called the *cloacæ*. (Troja, p. 45.)

In another experiment, he had an opportunity of examining the above little spaces at the end of 48 hours; he affirms, that they were replaced by the large apertures, or *cloacæ*, of the new bone; (P. 47.) and that such openings were invariably formed in the place of the small incrustated spaces already described. (P. 58.) As Troja took notice, that no lymph was effused at these particular points, he was inclined to impute the circumstance to a defect in the ossification, and, perhaps, to the death of some parts of the periosteum. Weidmann acknowledges, that the mode, in which the formation of the *cloacæ* happens, is exceedingly obscure; and expresses his belief, that Troja's account of it approaches the nearest to the truth. But, says he, one thing is certain, namely, that these openings have no other use, but that of conveying outward the pus, which collects in the cavity, and the small bony fragments, since, as soon as every atom of dead bone has passed out, they diminish, and, at length, are totally obliterated. (Weidmann *De Necrosi Ossium*, p. 36.)

It is a remarkable circumstance, in the history of necrosis, that, in favourable instances of the disease, the inflexibility and firmness of the limb are preserved, during the whole of the process, by which the new bone is formed. Consequently, the new bone must have begun to grow, and have acquired firmness before the old bone separates, or is absorbed. Were this not the case, the limb must become flexible and useless, the moment the dead bone is removed. Another consequence of the new bone being formed, before the removal of the old one, is that the former must surround and include the latter. For, since the lifeless portion of bone completely occupies the space between the two living ends, these cannot be immediately connected by the new bony matter. The connexion can alone be completed by the new bone being deposited on the outside of the old one, from one end to the other, and attaching itself to the portions which still remain alive. The new bone must also be necessarily larger, than the old one, because

externally situated, and hence the affected limb, after the cure is complete, will always continue larger, clumsier, and less shapely than the other. The length of it, however, remains unaltered, because the old bone retains its attachment, while the rudiments of the new bone are lying on its outside, and connect the living ends of the old one, by an inflexible mass, equal in length to the portion, which is destroyed.

Thus we see, that, in the process, which nature follows in the formation of the new osseous shell, the old bone serves as a mould for the new one, and the first step of the process is to surround the old bone with an effusion of coagulating lymph. (See *Russell on Necrosis*, p. 2—7.)

When the sequestrum is thrown off slowly, the inflammation is moderate; but, when it separates quickly, while the new bone is in a soft state, the detachment is always preceded by severe inflammatory symptoms, and followed by a temporary loss of the natural firmness of the limb. This premature separation of the sequestrum often occurs in necrosis of the lower jaw, and the chin consequently falls down on the neck. In certain cases, the sequestrum separates at each end from the living portions of the old bone, before the new osseous shell has acquired firmness, so that the limb feels as if it were broken in two places. (*Russell*.)

Let us next consider the states and circumstances of necrosis, in which the art of surgery may be advantageously exerted in the assistance of nature, and the means which may be employed for this purpose.

A common error of medical and surgical practitioners is always to impute the cure of every disease to whatever remedies happen to be employed, and successes are too often boasted of, the merit of which belongs entirely to nature. It is, indeed, not very unfrequent to hear remedies panegyrically spoken of, which counteract the salutary efforts of nature, who, in this case, is obliged to overcome both the disease, and the irrational treatment, which is applied to it. As Weidmann observes, this erroneous mode of considering things has happened particularly often amongst surgeons who have had cases of necrosis under their care, all of whom boast of the cures, which they have accomplished, although some employed absorbent earths, others, aromatics; some, spirituous applications; others, balmy remedies; some, acids; others, caustics; and, some, armed with a wimble, made numerous perforations in the dead bone; while many others rasped the part, or attacked it with the trepan, cutting forceps, the gouge and mallet, or even the actual cautery; and a certain number did nothing more, than apply dry lint. Nature, who was favourable to all, did her own work in silence, whatever

were the remedies employed for her assistance, whether mild and inert; acrid and corrosive; or hurtful and improper.

We have already noticed, that a dead portion of bone separates from the living exactly in the same way, as gangrenous soft parts spontaneously drop off, without the interference of art. The separation happens precisely at the points, to which death has extended; limits, which are well understood only by nature, and of course can be measured only by her. Art would incur great risk of either going beyond them, or else of not reaching them at all. Perhaps, it may be deemed unsafe to confide the process of separation, or exfoliation, to nature. But, in what other manner could it be more safely accomplished, without hemorrhage, or pain to the patient—without any risk of a recurrence of inflammation, or of a fresh necrosis?

Is there reason to fear, that, when every thing is left to nature, the separation cannot be finished till after a very long period of time? It is true, says Weidmann, that the process frequently requires a considerable time; but, as the vitality of the bones is not possessed of much energy, and their component parts strongly cohere, slowness is inevitable in an operation, which depends entirely upon the vital power. What is it then which surgery can do to accelerate the process?

Will any of the above-mentioned topical applications have this effect? They are put upon the inert surface of a dead piece of bone, in which no vital power, or action, can be again excited. When acrid, they prove irritating, inflaming, and destructive of the neighbouring flesh, without any utility—and cause pain to the patient, which is compensated by no good. Would the perforations, recommended by Celsus, Belloste, and many others, have the desired effect? If, says Weidmann, they are confined to the dead bone, they cannot have more effect, than the scarifications, which were formerly practised by ignorant surgeons in cases of gangrene; and, if they extend to the living bone, this will be injured, or at least run the risk of being so. Lastly; Weidmann demands, if the separation can be accelerated by the actual cautery, which cannot act upon every point of the necrosis, and which, unless applied with the greatest precautions, will burn the subjacent parts, and bring on a new attack of inflammation, without forwarding the exfoliation in the smallest degree?

Of what use can rasping and scraping instruments be, which act merely upon the dead part? Or will the gouge, and other cutting instruments do more good? They cannot take away the whole of the dead portion, without injuring the adjacent living bone, and causing a risk of

another necrosis. And, if they leave any pieces of the old dead bone behind, nature will be as long in effecting the separation of these, as she would have been in detaching the entire necrosis.

Weidmann mentions a case, which occurred in the hospital St. Roch at Mentz. A man's legs were seized with mortification, in consequence of exposure to cold; the whole of the dead parts separated; and the bones were sawn through on a level with the living flesh. A portion of the end of each bone, however, was afterwards thrown off altogether by nature, and Weidmann thence concludes, that the previous use of the saw had been fruitless. Weidmann then cites another case of mortification of the leg and half of the thigh, which was the consequence of a putrid fever. The leg sloughed away, leaving the lower portion of the thigh-bone uncovered and projecting. Under a tonic plan of treatment, this part of the bone spontaneously separated. As, however, a considerable quantity of integuments had been destroyed, the ulcer was slow in healing; but, it cicatrized at last, and the young woman continued well long afterwards.

Weidmann has quoted the memorable case, in which Mr. Charles White first sawed off the upper part of a diseased humerus. (See p. 49 of this Dictionary.) As, in this instance, nature accomplished of herself the separation of another dead portion of the same bone, two months after the operation, Weidmann seems disposed to think the cure would have happened equally well without it.

In cases of slight superficial necrosis, surgeons have frequent opportunities of trying every kind of topical application; and when the cure takes place, during the use of any of them, the benefit is ascribed to whatever happens to be in use. But, says Weidmann, in numerous more serious examples of necrosis, it is impossible to make these applications reach the whole surface of the dead bone; but, notwithstanding this circumstance, the separation is not impeded. Some exfoliations happen, without our knowing of their occurrence, and without a thought having been entertained of promoting them by any vaunted applications. We even see necroses separate, whose situation rendered them inaccessible to our remedies; such are the necroses, which occur within the long bones, and comprehend the whole of their cylindrical shaft or body. What surgeon shall presume to boast of his having effected by topical applications, the separation of the whole lower jaw-bone; a thing, which nature has very frequently accomplished? And, when, as often happens, the entire diaphysis of the thigh-bone, tibia, or other

long bone, comes away; or, split longitudinally, such bone loses a half of its cylinder; how is it possible for any topical applications to reach every point, at which the separation occurs?

The internal remedies, such as assa-fœtida, madder, sarsaparilla, hemlock, belladonna, onopordum, lime-water, &c. recommended by numerous practitioners, have in reality no direct efficacy in promoting the separation of necroses: if, says Weidmann, they do any good, it can only be by their tonic and alterative qualities, or rather by keeping the patient amused, so as to gain the requisite time for the completion of the process of exfoliation. The employment of all these ineffectual means, Weidmann conceives, must have originated from ignorance of the process, followed by nature in separating dead portions of bone, and from ascribing to the arterial pulsations, or the power of the granulations, what certainly depends upon the action of the absorbent vessels.

A question here naturally presents itself—Would there be any utility in exciting by stimulants the action of the lymphatic vessels, in order to accelerate the separation, of which it is the efficient cause?

Weidmann thinks, that very beneficial effects might result from the plan. But, he asks, what means should be used for this object? Cold? Purgative medicines? Repeated vomits? Squills? Camphor? Neutral Salts? Issues? (*Vid. Wrisberg, Comment. Soc. Reg. Gött. Vol. 9, p. 136, 1789.*) He adds, that, perhaps, many valuable discoveries will hereafter be made on this subject.

The reasons already detailed, and a variety of experiments successfully made by Weidmann, lead him to set it down as an established principle, that the separation of a necrosis is almost entirely the work of nature, and that surgery can do very little in the business.

Ignorance of this important fact paved the way to the wrong practice of making incisions, for the purpose of exposing the whole surface of a necrosis, immediately the existence of the disorder was known. As such incisions very soon closed up again, so as to leave only a small outlet for the matter, they were in many cases repeatedly practised before the dead bone became loose.

The avowed design of the incisions was to make room for the topical remedies, which were to render the exfoliation quicker; but, as these remedies possess no real efficacy, it follows, that making incisions, before the dead bone is loose, only torments the patient, without producing the least benefit.

The orifices of the ulcers, then, which allow the discharge to escape freely, are,

says Weidmann, sufficient as long as the fragments of bone are not entirely detached, and the surgeon should all this period abstain from the use of the knife.

Although Weidmann condemns every mode of treatment, which is inefficacious, painful, and sometimes even hurtful, he would not have it supposed, that he altogether rejects all assistance from medicine. On the contrary, he approves of all those means, which are consistent with the views of nature, which really assist her, and do not tease the patient to no purpose. In short, says he, *the indications are limited to removing the original cause of the disease; to alleviating the symptoms; to supporting the patient's strength, and improving the state of the constitution, in whatever respect it may be bad; and, lastly, removing the dead portions of bone, when they become loose.*

Above all things (continues this sensible practitioner) the surgeon must not regard every piece of exposed bone, as necessarily affected with necrosis, and, in consequence of such idea, have recourse to acrid, drying, caustic applications. Such means are not only useless, but absolutely pernicious; because they may actually cause a necrosis, which did not exist, before they were used, and which would not have taken place at all, if only mild simple dressings had been employed.

When the disease presents itself with violent symptoms, the inflammation and fever being intense, the severity of the case is to be assuaged by low diet, antiphlogistic remedies, emollient applications, and venesection in moderation, the disease being one which is of long duration, and apt to wear out the patient's strength. Here, perhaps, topical bleeding ought always to be preferred to venesection. When the necrosis has arisen from syphilis, scrophula, or scurvy, &c. the medicines, calculated for the cure of these affections, must be exhibited, ere any favourable changes can be expected in the state of the diseased bone.

Lastly, it is the duty of the practitioner to extract the fragments of dead bone, in order that the deficiencies produced by them may be filled up, and the ulcers of the soft parts heal.

Nature, who succeeds by herself in detaching the dead pieces of bone, can do very little in promoting their passage outward. Frequently, indeed, she has no power at all in this process, and it is only from surgery that assistance can be derived. When a dead piece of bone is still adherent at some points, its extraction should be postponed, until it has become completely loose. If it were forcibly pulled away, there would be danger of leaving a part of it behind, which must have time to separate, ere the cure can be accomplished.

But, when a fragment is entirely detached, and the orifices of the sores are sufficiently large, it is to be taken hold of with a pair of forceps, and extracted.

When the ulcer has only a very narrow opening, suitable incisions must be practised, in order to facilitate the removal of the loose dead bone.

Sometimes, the dead fragment protrudes from the ulcer, and projects externally, so that, if loose, it admits of being taken hold of with the fingers and removed. In this way, Weidmann took away a large dead piece of the humerus, which protruded nearly two inches out of an ulcer in the middle of the arm. The patient was a young lad, 14 years of age; and the limb concave within, convex externally, thicker, and one inch shorter than its fellow. He got quite well three weeks after the removal of the dead bone.

We have already adverted to the example, recorded by Weidmann, in which a shoemaker removed by himself nearly the whole body of the tibia. Doubtless, the projection of the bone, and its looseness, enabled the man to do this easily with his fingers. But, there are cases, which present more difficulty: such are those, in which the sequestrum is included in a cavity, either of the original, or new bone.

The old surgeons were in the habit of amputating limbs, which were in this state; although instances were not wanting in their days to prove the possibility of relieving the disease, without amputation. This blameable custom of removing every limb, thus affected, is justly exploded from modern surgery. Albucasis was the first, who attempted to cure such a case of necrosis, by the judicious employment of the knife and saw. (*Lib. 2, cap. 88.*) The same kind of practice was successfully adopted in two instances by the celebrated Scultetus. (*See Armament. Chirurg. Tab. 46, and Obs. 81.*) This commendable method, however, afterwards fell into disuse, until M. David, by twenty examples of success, refuted all the objections which had been urged against it. (*P. 197.*) Since the period of this distinguished author, the practice has been imitated by all enlightened surgeons, so that the case is no longer regarded, as a disease necessarily requiring amputation. M. Bousselin has cut out the sequestrum eight times from the tibia, and four times from the thigh-bone, with perfect success. (*Vid. Mém. de la Société Royale de Médecine, Tom. 4.*)

The method consists in exposing the bone, and making in it an opening of sufficient size for the removal of the loose dead fragments.

Experience has proved, not only that patients, affected with necroses, easily bear this operation, but, also, that, after

its performance, the ulcers commonly heal very favourably, the health becomes re-established, and the functions of the part affected are hardly at all impaired.

Surgeons, however, are not indiscriminately to choose any period for doing the operation. If they are too hasty, they will run a risk of finding the dead portion of bone still adherent to the adjacent parts; and, if they delay too long, the patient may be irrecoverably reduced, while the new bone, on account of the hardness which it has now acquired, cannot be so easily perforated.

Patients are met with, who have been afflicted with necrosis several years. In such cases, great circumspection is necessary, and the practitioner should carefully endeavour to ascertain, that the dead pieces of bone have not been absorbed, or come away piecemeal in the discharge, lest an useless operation should be done, as once happened in the practice of M. Bousselin. (*Mém. de la Société Royale de Médecine*, T. 4, p. 304.) Therefore, when the disease is of long continuance; when the discharge is much less than it was at the commencement; when small pieces of bone have at times been voided; and the sequestrum cannot be felt with a probe; it is doubtless, says Weidmann, most prudent to abandon all idea of operating, and allow nature to finish what she has so well begun. In short, when the sequestra are undergoing a gradual absorption, without ever making their appearance externally, or giving any considerable disturbance to the constitution; or, when the dead bone is making its way outward without occasioning urgent inconveniences; the surgeon should interfere very little with the natural progress of the case. When the dead bone does not tend to make its way through the skin, but lies quietly concealed in the new osseous shell, the occurrence of extensive suppurations may be prevented, by occasionally applying leeches, and keeping open a blister with the savine cerate, as recommended by Mr. Abernethy in his lectures, and Mr. Crowther, in his work on the White Swelling. The blister will, at the same time, have great effect in promoting the absorption of the sequestrum, and, of course, in accelerating the process of cure.

If the surgeon operate as soon as the sequestrum becomes loose, he will find the new bone so soft, that it can be divided with a knife; a circumstance, which materially facilitates and shortens the operation.

Keeping in mind the foregoing precepts, the surgeon is to begin with exposing the bone, in which the sequestrum is contained. When the bone lies immediately under the skin, Weidmann recommends making such incisions as will

lay bare the whole of its surface, and when its situation is deeper beneath the muscles, he even sanctions cutting away as much of the flesh, as may be necessary to allow the instruments to be freely worked upon the bone. I cannot, however, see the propriety of this advice: exposing the whole surface of the bone in the first instance, before it is known, whether the saw need be so extensively used as to require such a denudation, certainly appears irrational. And, as for cutting away any portions of muscle, this can be no more necessary here, than it is in the operation of trephining. But, it is unquestionably proper to make with the bistoury sufficient space for the use of whatever instrument is employed for the division of the bone. Yet, it is only necessary to make this exposure in the first instance in one place. The surgeon can afterwards enlarge the incision, or practise others, as circumstances may indicate. The surface of the bone being brought into view, if the cavities, in which the dead fragments lodge, present apertures, which are too narrow, these apertures must be rendered larger by means of small trephines, or saws constructed on the principles of those described by Mr. Hey, of Leeds. With such instruments the pieces of bone, extending across the above openings, and impeding the extraction, may also be removed.

But, when the preceding cavities are closed on every side, and it is impossible to reach into them in any other way, than through the cloacæ, a trephine is to be applied, which must comprise within its circle a half of the fistulous opening. The crown of the trephine, however, must not be broader than the cavity of the bone, nor yet narrower than the sequestrum.

If, after making a perforation in this manner, the sequestrum should be found too large to pass through the opening, a small saw must be employed for enlarging the aperture.

When the bone is so hard and thick, that it cannot be well cut with a saw, the surgeon has the sanction of authority, and experience, for using a gouge and mallet.

When the sequestrum is found to be very large, it will be necessary to expose more of the surface of the bone by incisions. In this sort of case, Weidmann recommends applying the trephine to the upper and lower parts of the cavity, and then cutting away the intervening portion of bone with the saw, or gouge. But, there can be no doubt, that a more prudent way would be to go on with the enlargement of the aperture in the bone, at the place where the first perforation took place, if the sequestrum presented itself equally well there, because, by proceeding in this manner, the surgeon might discover, that the dead fragment could be

taken out, without so great a destruction of bone, as is caused in the other mode; and, if this were not to be the case, no harm is done, as the necessary removal of bone can be continued.

When the bone, which includes the sequestrum, is a new production, and the operation is not too long deferred, the soft state of the bone will enable the operator to perform the needful excisions with the bistoury alone.

When the sides of the cavity, in the original bone, are thin, fragile, and pierced with numerous holes, the surgeon can break away a sufficient portion with a pair of forceps.

When several sinuses exist in the bone, each may be dilated, in the manner which seems most advantageous.

Sufficient openings having been made into the cavities including the sequestra, the next object is to extract these dead portions of bone. In accomplishing this part of the operation, Weidmann particularly advises two things; first, that no piece of the sequestrum be left behind; secondly, that no injury be done to the membrane, which lines the cavity, in which the dead bone is lodged.

This author observes, that there are examples, in which the vicinity of certain parts impedes the surgeon from making an opening in the bone, large enough for the extraction of a voluminous sequestrum in an entire state. In this circumstance, he recommends the sequestrum to be broken into pieces by any convenient means, and the fragments to be separately removed.

Weidmann has recorded an extremely interesting case to prove how much may sometimes be effected by taking away the sequestrum. A man, 34 years of age, who had an internal necrosis of the tibia, with abscesses and œdema of the whole limb, and who was reduced to the lowest ebb of weakness, was put under this excellent surgeon's care. A perforation was made with a trephine in the upper head of the tibia; but, this opening not proving ample enough, it was enlarged with a small saw, and the gouge and mallet. The sequestrum was then extracted. The patient's state afterwards gradually improved, and in nine months he was completely well.

It is not to be dissembled, however, that cases do exist, in which amputation affords the only chance of saving the patient's life. In fact, it sometimes happens, that the cavities, in which the sequestra are contained, communicate with those of the neighbouring joints, which then become filled with matter, and caries attacks parts of the bones, to which the necrosis does not extend. On some occasions, the dead pieces of bone are very numerous, and each has a separate cavity; while, in other instances, the sequestra

lie so deeply, that a passage for their extraction cannot be prudently attempted. Sometimes, also, a necrosis is complicated with another disease in its vicinity. Lastly, such may be the reduced state of the patient's health, and the particular condition of the necrosis itself, that the constitution cannot hold out during the whole time, which would be requisite for the detachment of the sequestrum. Under circumstances like these, amputation is necessary, and ought not to be delayed.

Dupuytren, of Paris, removed the mental portion of the lower jaw, may be found in the *London Medical Repository*, Vol. 5, p. 432. The wound healed by the first intention, and the patient got quite well.

NEPHROTOMY. (from νεφρος, a kidney; and τεμνω, to cut.) The operation of cutting a stone out of the kidney; a proceeding which, perhaps, has never been actually put into practice. In the *Abrégé Chronologique de l'Histoire de France*, par Mézerai, and in the *Philosophical Transactions* for 1696, two cases of what is called nephrotomy are mentioned; but several circumstances in the accounts led Haller and others to conclude, that the operation alluded to in the first work, was nothing more than the high operation for the stone. With respect to the example in the latter work, the particulars are not detailed enough to prove that an incision was really made into the kidney. There is no doubt that stones have often been extracted from abscesses about the region of the kidney, after being touched with a probe. But, with regard to cutting into the kidney, the deep situation of this viscus, and the want of symptoms, by which the lodgment of a stone in it can be certainly discovered, will always be strong objections to the practice. When a stone, from its size, cannot pass from the kidney, and excites inflammation and suppuration, no doubt, the surgeon may make an incision into the tumour, and extract the calculus. In this sense, nephrotomy is certainly a practicable operation. Warner contends, that it can only be practised in such circumstances, notwithstanding whatever may have been said by Marchetti, or others, upon the subject. In such a case, the operation would not be attended with any greater difficulty, than the opening an abscess in any other part of the body. (See *Warner's Cases in Surgery*, p. 241, Edit. 4.)

NODE. A swelling of a bone; a thickening of the periosteum, or a fascia; or a tumour on a tendon, from a venereal cause. See *Exostosis*, and *Venereal Disease*.

NOLI ME TANGERE. A species of lupus, under which term Dr. Willan intended to comprise, together with the *noli me tangere* affecting the nose and lips, other slow tubercular affections, especially about the face, commonly ending in ragged ulcerations of the cheeks, forehead, eyelids and lips, and sometimes occurring in other parts of the body, where they gradually destroy the skin and muscular parts to a considerable depth. (*Bateman's Synopsis of Cutaneous Diseases*, p. 296, Edit. 3.)

Sir E. Home says, that the ulcers, for which he has been led to employ arsenic,

are named, from the virulence of their disposition, *noli me tangere*, and are very nearly allied to cancer; differing from it in not contaminating the neighbouring parts by absorption, but only spreading by immediate contact. Ulcers of this kind differ exceedingly from one another in their degree of virulence; but they are all so far of the same nature, that arsenic in general agrees with them, and puts a stop to their progress, while they are aggravated by milder dressings. (*Home on Ulcers*, edit. 2, p. 267.)

The disease generally commences with small tubercles, which change after a time into superficial, spreading ulcerations on the alæ of the nose, more or less concealed beneath furfuraceous scabs. The whole nose is frequently destroyed by the progressive ravages of this peculiar disorder, which sometimes cannot be stopped or retarded by any treatment, external or internal.

The specific ulcerations do not generally extend to the parts far within the nostrils; but, at the time that I am writing this article, there is, under Sir L. Harvey, in St. Bartholomew's Hospital, a curious example, in which the greatest part of the nose is destroyed, and the ulceration proceeds even through the front part of the palate into the mouth. The morbid process sometimes stops for a considerable time, and then is renewed with increased violence. The following case illustrates the nature of *noli me tangere*, and one mode of treatment, to which it yielded. Jane Chatillon, 45 years of age, was attacked, in the course of September, 1788, with an inflammation on the left ala of the nose. Some time afterwards the part ulcerated, which occasioned a troublesome and sometimes a painful itching: different means were unsuccessfully employed, and the case remained nearly in the same situation till the month of September in the following year. At this period, the ulcer spread very fast: the septum nasi, the muscles, and cartilages of both sides, were, in a short space of time, destroyed. The ulceration extended on the left side, on the loose edge of the upper-lip. This was the state of her case on her admission into the Hospital of St. Louis, in the month of October, 1789.

A poultice, moistened with aq. veg. was applied twice a day to the ulcer; a sudorific ptisan prescribed, and a pill, composed of one grain of calomel, and one grain of sulph. aurat. antimonii, ordered to be taken every day. From the fifth day, the inflammation lessened. No other sensible alteration took place till the 21st. The suppuration, that, till this time, had been black and putrid, now became white and inodorous.

On the 37th, the discharge was trifling,

and the ulcer being well deterged, was dressed with pledgets, dipped in a solution of verdigris and corrosive sublimate, in the proportion of six grains of each to a pint of water. On the 40th day, cicatrization began to take place, and was finished by the 60th.

Some time before it was completely cicatrized, an issue was made in the arm, which was healed up, without any inconvenience to the patient, six months after the cure. (*Parisian Chirurgical Journal*, Vol. 1.)

One of the best external applications to *noli me tangere* is the following lotion; $\mathcal{R}$. Kali arsenicati, gr. iv. Aq. menthæ sativæ $\mathfrak{z}$ iv. Spiritus vini tenuioris $\mathfrak{z}$ j. Misce et cola. I have seen several cases in St. Bartholomew's Hospital, which were either cured or seemed disposed to get well with this useful application. The solution of arsenic, which Sir E. Home has always used, is made by boiling white arsenic in water for several hours, in a sand-heat. When given internally, the dose is from three to ten drops; when for external application, a dram is to be diluted with $\mathfrak{ss}$ of water; and this solution is gradually made stronger, as the parts become accustomed to it, till it is of double strength. However, this mode of using arsenic is by no means a well regulated one; and Plunket's caustic (see *Arsenic*) for outward employment, is not nearly so neat an application as the above-mentioned lotion. At St. Bartholomew's Hospital, arsenic is administered internally in the following formula: $\mathcal{R}$. Kali arsenicati gr. ij. Aquæ menthæ sativæ $\mathfrak{z}$ iv. Spiritus vin. ten. $\mathfrak{z}$ j. Misce et cola. Dosis $\mathfrak{z}$ ij. ter quotidie. In this way, the quantity of arsenic is nicely determined. We shall only just add, with regard to this medicine, that, both as an external application and an inward remedy, in cases of *noli me tangere*, it perhaps deserves the highest rank. One scruple of the argentum nitratum, dissolved in half an ounce of distilled water, makes a very good application, which, although generally inferior, in point of efficacy, to arsenical ones, in the present disease, occasionally does good, when nothing else seems to produce any benefit. The above case makes us acquainted with another lotion, which deserves further trial. All fluid remedies must be applied to the part, by dipping little bits of lint in them, placing these on the ulcerations, and covering the whole with a pledget.

The ointments, which seem most likely to prove useful applications to *noli me tangere*, are the unguentum hydrargyri nitrati, the unguentum picis, and unguentum sulphuris. As far as my experience extends, they are generally less efficacious than lotions in the present cases; but, in particu-

lar instances, they prove superiorly useful, and it deserves especial notice, that surgeons can often make no progress against this inveterate disease, unless they apply a different sort of dressing every day; sometimes, a lotion; at other times, an ointment. The little ulcers may occasionally be touched with the *argentum nitratum*. The small furfuraceous scabs, which are continually forming on the part affected, should be softened with a little of the *unguentum spermatis ceti*, and removed with as much tenderness as possible.

We have already remarked, that arsenic is a good medicine to be given internally, and the best mode of exhibiting it has been already explained. Another medicine, which is often useful in these cases, is what is known by the name of Plummer's pill, or the compound calomel pill. *R. Hydrargyri Submuriatis, Sulphuris Antimonii præcipitati, singulorum gr. xii. Guaiaci gummi resinæ, gr. xxiv. Saponis quod satis sit. Misce; fiant pilulæ duodecim. Dosis una bis quotidie.*—In other instances, we may try the decoctum ulmi, or sarsaparillæ, with one of the following pills thrice a day: *R. Hydrargyri Submuriatis gr. vj. Succis spissati cicutæ 3j. Misce; fiant pilulæ duodecim.* The hydrargyrus sulphuratus has occasionally been given, as an alterative medicine, for the relief of *noli me tangere*; with what good effect I cannot pretend to say.

In three, or four less severe cases of lupous tubercles on the face, which had made no progress towards ulceration, Dr. Bateman saw the solution of muriate of barytes, taken internally, materially amend the complaint. Sometimes, also, a separation of the diseased parts from the sound has been effected with the knife, or caustic, and the progress of the complaint been stopped. (*Synopsis of Cutaneous Diseases*, p. 296, Edit. 3.)

NYCTALOPIA. (from *νύξ*, night; and *ὤψ*, the eye; or *ὀπτω*, to see.) An affection of the sight, in which the patient is blind in the day-light, but sees very well at night.

Nyctalopia, *visus nocturnus*, or day-blindness, vulgarly called owl-sight, (says M. Lassus) is an affection in which the patient either cannot see at all, or sees but very feebly, objects, which are in the open day-light, or situations where there is a strong light; but discerns them very well, when they are in a darkish place, or at sunset, or in the night-time, if not immoderately dark. (See *Pathologie Chirurgicale*, T. 2, p. 539—540.)

The Greek physicians are divided in their opinions concerning the now uncommon disease of nyctalopia. Hippocrates expressly says, "we call those nyctalopes who see by night." The author of *Defin. Medic.* "that they see nothing in the

day-time, but have their sight by night." On the contrary, Paulus Ægineta, and Actuarius are as explicit in asserting, that they have their sight perfect in the day-time, but are blind by night. Ætius is of the same mind, though he is thought to favour the contrary opinion, when he says, "they see better by night than in the day, and if the moon shines they are blind." The author of *Isagoge* embraces both opinions, when he says, "they call those nyctalopes who, in the day-time, see more obscurely, at the setting of the sun more clearly, but, when it is night, much better; or, on the contrary, by day they see a little, but, in the evening, or at night, they are blind." Galen explains the word by a night-blindness. Pliny, Varro, Nonius, Festus, Celsus, and other Latin writers, give equally opposite definitions of the disorder. Dr. Pye questions, whether these two descriptions of nyctalopia, so diametrically opposite to each other, may not be reconciled by considering the disorder as an intermittent one. The difference then will only consist in the different times of the approach of the disease; that of Hippocrates came on in the morning; that of Ægineta, in the evening; both were expressly periodical, and the distance of time between the paroxysms, in both, was respectively the same; a whole day, or a whole night. The various shapes, in which intermittents appear, very much favour, says Dr. Pye, such an opinion; and the apparent success of bark in the case, which he has related, notwithstanding the unfavourable circumstances of the evacuations his patient laboured under, and the consequent necessity of its disuse, seem to confirm it in this gentleman's mind. (*Med. Obs. and Inq. Vol. 1.*)

In this work, I shall follow Callisen, Richter, and the best modern surgical writers, in calling day-blindness, *nyctalopia*, and night-blindness *hemeralopia*. (See Callisen, *Syst. Chir. Hodiernæ*, Vol. 2, p. 362; and Richter's *Anfangsgr. der Wundarzn.* B. 3, p. 479.)

Nyctalopia, in the sense of day-blindness, is a very rare disease, in comparison with hemeralopia, which is a very common disorder in warm climates. According to Dr. Hillary, there are a people in Siam, in the East Indies, and also in Africa, who are all of this cat-eyed species, or subject to the disease of being blind in the daytime, and seeing well by night. (*Mod. Univ. Hist. Vol. 7.*) The same author notices the general rarity of the disorder, and mentions his having met with but two examples of it.

With respect to the causes of the complaint, Dr. Hillary observes, that it proceeds from too great a tenderness and sensibility of the iris and retina. M. Lassus thinks

the causes may be of different kinds. "If, for instance, (says he) there were a very small opacity, like a point, exactly opposite the pupil, or centre of the crystalline lens, the pupil, contracting in the open daylight, would stop the entrance of the rays of light into the eye, and a day-blindness arise, which would be diminished by the expansion of the pupil in the shade. Here, the cure would depend upon the removal of the opacity.

"Persons, whose pupils do not move freely, but remain much dilated, and do not sufficiently contract in light situations, are also affected with nyctalopia; for, so large a quantity of the rays of light pass into their eyes, that it serves rather to destroy, than assist vision. Such persons see tolerably well, and better than the preceding class of patients, in a darkish place, and they ought to wear green spectacles in the day-time, in order to weaken the impression of the rays of light. When a person is shut up a long while in a dark place, the pupils become habitually dilated, and if he exposes himself suddenly and incautiously to a strong light, the eyesight may be destroyed. There are other individuals, who, from excessive sensibility of the iris, cannot bear much light: their pupils instantly contract, and close. This case (continues M. Lassus) may be brought on by too great an indulgence in venereal pleasures, and in persons, who have debilitated their constitutions during their youth." The same author mentions other cases, which seem to depend upon a species of irritability of the iris. In one instance, an issue in the arm effected a cure, and he mentions the utility of blisters. He admits likewise with Dr. Pye cases of intermittent or periodical nyctalopia,

which begin regularly in the morning, and go off in the evening, the patient continuing blind, whether he keep himself in a dark or a light place. The cause of these instances, which, he observes, are very uncommon, is generally seated in the primæ viæ, and requires emetics, resolvents, purgatives, and bark. (See *Pathologie Chirurgicale*, Tom. 2, p. 540—542. Also *Richter's Anfangsgr. der Wundarzn.* B. 3. p. 481.) In 1787, Baron Larrey met with a case of day-blindness in an old man, one of the galley slaves at Brest, who had been shut up incessantly for thirty-three years in a subterraneous dungeon. His long residence in darkness had had such an effect on the organs of vision, that he could only see in the dark, and was completely blind in the daytime. (See *Mém. de Chir. Militaire*, T. 1, p. 6.)

Nyctalopia may perhaps sometimes depend on a peculiarity in the structure and organization of the eye; by reason of which, the quantity of light, which only suffices for vision in an eye of natural formation, proves too abundant for a nyctalops, and absolutely prevents him from seeing at all. We know, that in the eye there is a black substance, named the *pigmentum nigrum*; one supposed use of which is to absorb the redundant rays of light, which enter the pupil. A deficiency of this, may certainly account for a nyctalops being blinded with the day-light, and seeing best at night.

In addition to the few suggestions already offered above, on the mode of curing day-blindness, I have not been able to collect any further information on the subject, worth noticing.

For an account of nyctalopia, in the sense of night-blindness, refer to *Hemeralopia*.

O.

ŒDEMA. (from *oidew*, to swell.) The ancients understood, by this term, all kinds of tumours; but, it is now restricted to a swelling arising from an extravasation of an aqueous fluid in the cellular substance of a particular part; for, when the affection is more extensive, and especially when it is also accompanied with a general dropsical tendency, it then becomes a medical case, and receives the name of *anasarca*. An œdematous part is usually cold, and of a pale colour; and, as it is little, or not at all elastic, it pits, as surgeons express themselves, or, in other words, it retains, for some time, the mark of the finger, after being handled, or pressed. Œdematous swellings are often con-

nected with constitutional causes. In many cases, however, they seem to be entirely local affections, arising from such causes as only act upon the parts, in which the swelling is situated. Thus we observe, that after violent sprains of the wrist, or ankle-joint, the hands and feet often become œdematous; and limbs are frequently affected with œdema, in consequence of the return of blood through the veins being obstructed by the pressure of tumours on them, or that of splints, bandages, &c. Pregnant women are known to be particularly subject to œdema of the legs, owing to the pressure of the gravid uterus on the iliac veins. Persons who have been confined in bed, with fractured

thighs, or legs, generally have more or less œdema in their feet and ankles, on first getting up again; and the affection in these cases, is probably quite dependent on loss of tone in the vessels of the limb.

In the treatment of œdema, great attention must always be paid to the nature of the cause, in order to determine whether the disease originates from a mere local, or a general constitutional affection. When it depends on the pressure of a tumour on the veins, as we often see happen in cases of aneurisms, the effect cannot be got rid of till the cause is removed; and the aneurismal swelling must be lessened, before the œdematous one can admit of the same beneficial change. When œdema is the effect of vascular weakness in a limb, in consequence of sprains, contusions, &c. the best means of relief is, to support the parts affected, with a laced stocking, or a flannel roller, while they are also to be rubbed with liniments, and bathed with cold spring water, till they have perfectly recovered their tone.

With regard to the œdema attendant on the advanced state of pregnancy, a complete cure cannot be expected till after delivery. The affection is generally more considerable in the afternoon, than the morning, owing to the different effects of an erect and a recumbent position. Some relief may be obtained by keeping as much as possible in a horizontal posture; and, when much inconvenience and pain are felt, the parts may be fomented with any aromatic or spirituous application.

Œdema is often one of the symptoms of suppuration; and, when the matter is very deeply situated, sometimes leads to its discovery. The truth of this remark is often seen in cases of empyema.

There is a species of œdema accompanied with a degree of heat, pain, &c. in the part, and which, in short, seems combined with phlegmon. In this case, saturnine lotions, the application of leeches, and the exhibition of saline purgatives, are proper. An erysipelatous œdema is also met with, in which the treatment should very much resemble what is explained in the article *Erysipelas*.

ŒSOPHAGOTOMY. (from *œsophagus*, and *τομή*, to cut.) This operation consists in making an incision into the œsophagus, in order to take out of this tube foreign bodies, which lodge in it, and which can neither be extracted through the mouth, nor pushed down into the stomach, and whose continuance in the œsophagus would occasion fatal symptoms.

As the œsophagus is deeply situated, and covered by very important parts, such

as the trachea, nerves, and considerable blood-vessels, every operation, the object of which is to make an opening into this tube, has always been regarded as exceedingly dangerous, and was even, for a long while, quite proscribed. However, although every rational practitioner agrees, that this proceeding should never be resorted to, without some most urgent cause, yet, if a case were to present itself, in which the œsophagus was so obstructed, by some extraneous substance, that no food could absolutely pass into the stomach, or if, in consequence of an accident of the same nature, respiration were impeded in a manner imminently dangerous to life, doubtless the uncertain chance of the operation should be preferred to the certainty of a fatal event without it. Many instances of the œsophagus being accidentally wounded, have been known to end well. Mr. B. Bell saw a man, who, in attempting to kill himself, by cutting his throat, cut through a great part of the trachea into the œsophagus. Bohnius' relates the case of a man, wounded in the same way, whose wound in the œsophagus was quite manifest, as every thing which the patient attempted to swallow came out of it. Both the patients, just mentioned, got well, and many similar examples are on record.

Guattani, a surgeon at Rome, published, in the third volume of the *Mem. de l'Acad. de Chirurgie*, a dissertation on the present subject. After explaining the manner of performing this operation, he relates some experiments made on dogs, which succeeded very well. He practised the plan also on the dead subject, in such a manner as to make it demonstrable, that the method was practicable on the human body. What is still more conclusive, the operation was actually done twice, on living subjects, with perfect success. The following is the account of these facts, as recorded in the *Mem. de l'Acad. de Chirurgie*.

"In the month of May, 1738, M. Goursauld, a surgeon at Coussat-Bonneval, in Limousin, was called to a man, who had swallowed a bone, an inch long, and six lines broad. M. Goursauld made various attempts to make this foreign body pass down into the stomach. Not being able to succeed, however, and the bone being felt on the left side, he determined to cut upon it, and try to extract it. An incision having been made, the bone was easily extracted, no bad symptoms followed, and the wound healed, with the aid of an uniting bandage. Care was taken to give the patient no food for six days, but to nourish him with glysters. A similar operation was performed, with equal success, by M. Rolland, surgeon-major of the regiment of Mailly." (*Memoires de l'Académie de Chirurgie*, Tom. 3.)

Guattani, in this memoir, observes, with several other anatomists, that the œsophagus is always situated, not directly between the trachea and vertebræ, but rather more towards the left than the right. This fact would always make a surgeon, when he deems œsophagotomy necessary, undertake it on the left side of the neck. The parts, which cover the œsophagus, from the middle and external part of the neck, to the upper part of the sternum, are the skin, fat, cellular substance, muscles proceeding from the sternum to the larynx, the thyroid gland, the thyroid arteries and veins, the trachea, the recurrent nerve, &c. Things thus circumstanced, Guattani recommends the following mode of operating. "The patient is to sit on a chair, with his head inclined backward, as far as may be thought proper, and held by an assistant, so that it can neither move backward nor forward. The operator, placed before the patient, after pinching up the skin on the right side, into a transverse fold, with the fingers of his left hand, while an assistant does the same to that on the left, is to make, with a straight bistoury, a longitudinal incision in the integuments, from the upper part of the sternum. He is next to divide the cellular substance, fat, &c. which he will find between the left sterno-hyoideus, and sterno-thyroideus muscles, and the trachea. By means of two double blunt hooks, he is to keep the edges of the wound asunder, and, on dividing the cellular substance at the side of the trachea, with his finger and a few strokes of the knife, he will see the œsophagus. A longitudinal incision is then to be made into the lowest part of it, with a straight knife; and this wound must afterwards be dilated upward, with curved, blunt-pointed scissars. If any difficulty should be experienced, the surgeon may employ a director, to facilitate the last object. Small curved forceps, similar to those used for extracting polypi, are then to be introduced into the œsophagus, for the purpose of extracting the extraneous substance. This canal having been opened in the place above specified, the foreign body may be extracted with these forceps, whether it be situated above or below the aperture made for the purpose. This kind of opening will even be useful, when the extraneous substance has passed so far that it cannot be extracted with forceps; for, with a bougie, or some other instrument, it may now be easily pushed down into the stomach.

"The operation finished, the dressing of the wound is a point, which merits a great deal of attention, in regard to the method pursued to unite it. This object has always been accomplished in the animals, on which my experiments were made. If comparative surgery have any

weight, it is certainly in such cases as the present one, in which the structure of the part seems to be almost the same. It is also proved by my experiments, that the œsophagus cicatrises very well, without contracting any adhesion to the adjacent parts. It is proper to observe, 1. That the integuments being cut, and the parts disengaged, if, by chance, the vein, which brings back the blood from the inferior part of the thyroid gland, and runs into the left subclavian, should be cut, the hemorrhage may be stopped with a dossil of lint, which is to be compressed by an assistant's finger, during the operation. The vein will afterwards be compressed by the uniting bandage, employed for healing the wound; but, otherwise, a ligature is to be used. 2. That, on separating the lips of the wound, the recurrent nerve may be seen, at a greater or lesser distance from the trachea. If, then, it should be foreseen, that it would be injured in separating the cellular substance, and making the incision into the œsophagus, it must be drawn out of the way, with the same hook which is employed for pulling aside the left lip of the wound. In the same manner, the trachea may be carefully drawn to one side with the right hook, if it should embarrass the operator in finding out the œsophagus; a thing which may be done without fear of seriously interrupting respiration. 3. That the œsophagus is to be opened, as near as possible to the trachea, especially at its upper part, where the arterial branch, which goes from the subclavian, to be distributed to the thyroid gland, sometimes runs. 4. That, if thought proper, the thyroid gland is to be separated from the left side of the trachea, when the foreign body, lodged in the œsophagus, requires a large incision, and, particularly, when this gland is very much swollen, as it would prevent a free view of the œsophagus. 5. That the œsophagus will be known to be opened, when the internal membrane, which is whitish, has been divided. 6. That the operation should be done with promptitude, when it is thought necessary, in order to avert the unpleasant consequences of inflammation of the œsophagus. 7. That the operation being done, the reunion of the parts is to be promoted, by simple dressings, and the uniting bandage.

"With regard to regimen, besides all the general remedies required in such cases, and every thing which a judicious practice indicates, I am of opinion, that it would be proper (as far as possible) only to give the patient, at intervals, a little broth, for the first three or four days after the operation, so as not to disturb the healing of the parts. And, as broth might cause some little disturbance of the wound, even nourishing glysters, which we know would suffice for the support of the patient

this short time, who, in such cases, is not much reduced." (*Guattani, in Mem. de l'Acad. de Chirurgie, Tom. 3.*)

Whenever nourishment is to be conveyed into the stomach, through a wounded œsophagus, a hollow bougie should be introduced, from one of the nostrils, down the passage, and liquid food injected through it, with a syringe.

ŒSOPHAGUS, FOREIGN BODIES IN. There are few situations, in which foreign bodies lodge more frequently, than in the œsophagus. The function of this tube explains the reason of this occurrence, and its nearness to the windpipe accounts for the danger of suffocation, whenever a foreign body above a certain size is lodged in it.

Foreign bodies, liable to stick in the œsophagus, are not only food, such as pieces of crust, or meat imperfectly chewed, but also various substances which are accidentally swallowed alone, or with the food, such as little bones, stones, pins, pieces of money, &c. These latter articles, by lodging in the pharynx, or œsophagus, may occasion very bad symptoms; and, if forced down into the stomach, may produce still worse effects. Hence, we should immediately try to extract them. For this purpose, the fingers are to be used, and if they cannot reach them, forceps must be employed. Some have recommended hooks, for the accomplishment of the object in view; others, various instruments, adapted to particular circumstances. The excitement of vomiting has been tried, and occasionally with success; but, it is not free from danger, and the most distressing symptoms have been brought on by it.

When such extraneous substances cannot be extracted, they must be pushed down into the stomach, with some such instrument as a large bougie, or a whalebone probang, fifteen or sixteen inches long; and, on the end of which, a piece of fine sponge is firmly fastened. Small bits of sponge, tied on the ends of some string, have also been used; the patient is to swallow them, and then take some drink. The sponge, expanded with the fluid, dilates the passage, and facilitates the descent of the extraneous substances into the stomach. But, when such bodies are, from their sharp-pointed, angular shape, or hurtful nature, likely to occasion perilous consequences, by being pushed down into the stomach, the plan must not be attempted. Hard, angular substances, and such things as pins and needles, which surgeons have not chosen, or not been able, to force down into the stomach, have often, after a time, made their way to the surface of the body, where an abscess has formed, out of which they have been discharged.

When hard bodies have been pushed, or have got of themselves, down into the

alimentary canal, their ill effects should be counteracted, and their passage through the bowels promoted, by giving the patient frequent draughts containing the oleum amygdalarum.

When foreign bodies, in the œsophagus, resist the different means employed for their extraction, or for propelling them into the stomach, where this method has been judged to be proper; when, at the same time, the pain which they occasion is not considerable; when they do not too seriously interrupt respiration, and leave sufficient room for the passage of aliment and drink; it is prudent to abstain from further attempts to displace them. They should be left to nature, while the practitioner should content himself with bleeding the patient a few times, exhibiting draughts containing the oleum amygdalarum, and employing glysters. But, when the lodgment of such foreign bodies dangerously obstructs respiration, by the pressure made on the larynx, an opening must be quickly made in the trachea, in order to serve for a time the office of the natural passage for the air. (*See Bronchotomy.*) As soon as the swelling subsides, another attempt may be made to move the extraneous substance. (*See L'Encyclopédie Méthod. Partie Chir. Art. Corps Etrangers.*)

There may be cases, in which death would certainly result from the continuance of a foreign body in the œsophagus, and if it could neither be extracted nor removed by common means, perhaps cutting into the œsophagus would be proper. (*See Œsophagotomy.*)

When some extraneous substances have been left to themselves, nature has sometimes succeeded in expelling them. They have excited ulceration in the part, where they were lodged, by which they have been loosened, so as then either to be ejected by vomiting, or, after descending into the stomach, to be discharged by stool. In passing any instrument into the œsophagus, the great skill lies in putting it at once directly against the posterior part of the pharynx, so as to avoid touching the epiglottis, and keeping it closely against the vertebræ all the way down. The knowledge of this circumstance may be of infinite service in passing probangs, bougies, &c. but, hollow bougies are introduced in a different way, viz. through one of the nostrils, down the pharynx. When thus employed, they may sometimes be allowed to remain in the passage very advantageously. They are extremely useful for the conveyance of food and medicines into the stomach, when the œsophagus has been wounded; and as the elevation and depression of the larynx, in the action of swallowing, produces immense disturbance of wounds of the trachea, they promise to be of infinite service in the latter cases.

ŒSOPHAGUS, STRICTURES OF.

As the œsophagus is required to be wider at one time, and narrower at another, in order to be fitted for conveying the different kinds of food into the stomach, it is nearly under the same circumstance, with respect to the formation of stricture, as the urethra. Strictures in the œsophagus are, for very obvious reasons, much less frequent than in the urethra. However, they are by no means uncommon, and produce symptoms even much more distressing and dangerous, than those, which ordinarily arise from analogous obstructions in the passage for the urine.

This disease has long been noticed by surgical authors, and Mr. Warner in particular has recited an instance of it, that proved fatal, the patient having become incapable of taking nourishment. (See *Cases in Surgery*, by J. Warner, F. R. S. p. 130, Edit. 4.)

Of course, the most remarkable symptom of a stricture in the œsophagus, is the difficulty of swallowing, which must be greater or less, according as the obstruction is more or less complete. Sometimes no solid food whatever can pass down into the stomach, and fluids can only descend with great difficulty, and in very small quantities. This is, in some instances, attended with considerable pain, which extends along the fauces to the basis of the skull, and through the eustachian tube to the ear. The pain sometimes returns at intervals, and lasts a considerable time, even when no effort is made to swallow. If a bougie of proper size be introduced down the pharynx, it will often be stopped by the stricture just behind the thyroid, or cricoid cartilage; for, from Sir E. Home's remarks, it appears that the obstruction is generally as high up as this situation. However, there are other cases, in which the obstruction is only of a spasmodic nature, and in these, a bougie may be passed quite down. It is curious, that strictures high up in the œsophagus, often occasion ulceration in this tube very low down towards the stomach, just as strictures in the urethra occasion ulceration in that passage towards the bladder. This is most apt to occur, when strictures of the œsophagus have been of long continuance, and may arise from the efforts in retching, which frequently comes on, and must strain the parts already deprived of their natural actions, and of the benefit of the secretions, with which they are lubricated in a healthy state. When such ulceration takes place, the characters of the original disease are lost; and when the ulceration extends upwards, the stricture itself may be destroyed. A bougie, introduced under such circumstances, will, in general, have its point entangled in the ulcer; and when so skilfully directed as to go down into the œsophagus, it will meet with a difficulty while it

is passing the commencement of the ulcerated part of the œsophagus, and another impediment where it leaves the ulcer, and enters the sound portion of the œsophagus below. These two resistances may lead to the supposition, that there are two strictures, while in fact there is not one, only ulceration as above described.

Strictures in the œsophagus are sometimes so complete, that swallowing even fluids is utterly prevented; the patient is obliged to have all nourishment injected *intra anum*, and in general soon perishes in a most emaciated condition.

Though any part of the œsophagus is liable to the kind of contractions forming strictures, the part immediately behind the cricoid cartilage, where the pharynx ends, and the œsophagus begins, is the most frequent seat of the obstruction. Those which are situated further down, do not so easily admit of being examined, and relieved by any surgical operation. Strictures of the œsophagus occupy very little extent of the passage, consist of a transverse fold of the internal membrane, and are attended with little thickening of the adjacent parts. These latter circumstances are such as render the disease capable of receiving relief either from simple or armed bougies.

There are two other diseases of the œsophagus, which have symptoms similar to those of strictures. One is a thickening of the coats of the œsophagus, which extends to the surrounding parts, and generally ends in a cancer, or an incurable disease. The other affection is an ulcer of the lining of the passage, commonly situated a little below the seat of the stricture, on the back part of the tube. In the early state, these diseases can only be distinguished from a stricture, by an examination with a bougie; afterwards their nature becomes clear enough from other symptoms which arise. Strictures also take place more commonly in young subjects; the other two diseases in the more advanced periods of life.

Sir E. Home has found, that a bougie can be more easily introduced into the œsophagus, when the tongue is brought forwards out of the mouth. This gentleman remarks, that when a bougie is passed, with a view of learning the nature of the case, and it passes down to the distance of eight inches, measuring from the cutting edge of the front teeth in the upper jaw, its extremity has gone beyond the usual seat of stricture. If it be withdrawn without any resistance, the aperture in the œsophagus must then be larger than the bougie employed. But if the bougie stops at the distance of six inches and a half, or even lower, it must be retained there with a uniform pressure for half a minute, so as to receive on its point

an impression of the surface by which it was opposed. If the end of the bougie retains its natural form, or nearly so, and there is an indentation on one side of it, or all round it, the surgeon may conclude there is a stricture. On the other hand, should the bougie descend without impediment, as far as seven inches and a half, and, when withdrawn, the surface of its point appear irregular and jagged, the disease is an ulcer on the posterior part of the œsophagus.

The mode of treatment adopted by Sir E. Home, consists either in occasionally passing a common bougie through the stricture, and employing one of larger size, in proportion as the dilatation of the obstruction will allow; or else in introducing an armed bougie at convenient intervals. Consult *Practical Observations on the Treatment of Strictures in the Urethra and Œsophagus*, Vol. 1, Edit. 3, 1805. Vol. 2, 1803, by Sir E. Home, F. R. S.

In spasmodic strictures of the œsophagus, blisters have been known to do good, and I have heard a most eminent surgeon express a strong expectation, that other strictures of this passage would be benefited, by feeding the patient through hollow bougies.

ŒSOPHAGUS, POLYPI OF. (See *Polypus*.)

OLEUM CAMPHORATUM. $\mathcal{R}$. Olei Olivæ. $\mathfrak{h}\mathfrak{j}$. Camphoræ $\mathfrak{z}\mathfrak{i}\mathfrak{v}$. Misce ut solvatur camphora.

Some practitioners employ this for promoting the suppuration of indolent, particularly scrophulous swellings, which are to be rubbed with the application once, twice, or thrice a day, according to circumstances.

OLEUM LINI. In surgery, linseed oil is often used as an application to burns, either alone or mixed with an equal quantity of the aqua calcis. It has also been applied to cancerous ulcers, as some assert, with considerable benefit.

OLEUM ORIGANI. The oil of marjoram is often used by surgeons for discussing ganglions: the tumours are to be rubbed with it two or three times a day.

OLEUM PALMÆ CAMPHORATUM. $\mathcal{R}$. Camphoræ $\mathfrak{z}\mathfrak{i}\mathfrak{j}$. Olei palmæ $\mathfrak{h}\mathfrak{j}$. The camphor is to be reduced to powder, and the palm oil, being melted, and suffered to become almost cold, is to be mixed with it in a mortar. This application is a mild topical stimulant: it has been used for promoting indolent suppurations, especially those of a scrophulous nature, which take place under the jaw, and are attended with a good deal of chronic induration at their circumference.

OLEUM RICINI. In such surgical cases as require the bowels to be opened with the slightest degree of irritation possible, the oleum ricini is the best and safest

medicine that can be given. The usual dose is one large table-spoonful, which must be repeated every two or three hours, till the desired effect is produced.

OLEUM TEREBINTHINÆ. Oil of turpentine is employed externally as a stimulating liniment, and a styptic. In the article *Liniment* may be seen some formulæ, in which turpentine is the most active ingredient. It is sometimes exhibited by surgeons internally, for the cure of gleans.

OLEUM TEREBINTHINATUM. $\mathcal{R}$. Olei Amygdalæ $\mathfrak{z}\mathfrak{ss}$. Olei Terebinthinæ gutt. $\mathfrak{x}\mathfrak{l}$. Misce.

In deafness, occasioned by defective, or diseased actions of the glandulæ ceruminæ, Mr. Maule directs a little of this oil to be dropped into the patient's ear, or applied at the end of a small dossil of cotton.

When a thin secretion takes place, the cure is also promoted by a small blister, which he orders to be placed as near the ear as convenient, and kept open by the common means. Of course, the savine cerate would now be preferred for this purpose. The meatus auditorius externus must also be cleansed every day with a lengthened bit of soft cotton, affixed to a probe. This is to be introduced into the passage, and twisted gently round, so as to wipe away the discharge. (See *Pharmacop. Chirurgica*.)

OMPHALOCÉ'LE. (from *ομφαλος*, the navel, and *κηλη*, a rupture.) A rupture, or hernia at the navel. See *Hernia*.

ONYCHIA. (from *ονυξ*, the nail.) An abscess near the nail of the finger. See *Whitlow*.

O'NYX. (from *ονυξ*, the nail.) A small collection of matter, situated under the cornea, in the anterior chamber of the aqueous humour, and so named from its being shaped like a nail. It is of the same nature as *Hypopium*, to which word I must refer the reader. Maître-Jean, Mauchart, and several other oculists, imply by the term *onyx*, a small abscess between the layers of the cornea.

OPHTHALMY. (from *οφθαλμος*, the eye.) Inflammation of the eye.

Ophthalmia is not only a consequence of several affections of the eye and adjacent parts, on the existence of which its continuance entirely depends; it is frequently, also, the primary complaint, and too frequently the fore-runner, of those irreparable diseases which deprive the patient of vision. Redness of the tunica conjunctiva; tumefaction of the eyelids; aversion to light; lancinating pain in the orbit; an itching, conjoined with a sensation of heat; and an uneasiness, seeming as if it arose from particles of sand in the eye; are symptoms forming the general inconveniences attendant on inflammations of

the eye. No part of the eye-ball can be considered as exempt from the attack of inflammation. Hence, in ophthalmy, not only the conjunctiva, the sclerotica, and the choroides, but the retina itself, may also be inflamed, as well as the surrounding parts, the palpebræ, the muscles in the orbit, and the lachrymal gland.

The grand distinctions of ophthalmy are into two species, viz. *acute* and *chronic*; the one arising, as Scarpa says, from an excess of stimulus, and re-action of the living solid; the other connected with debility, which is generally limited to the vessels of the parts affected, but sometimes extends to the whole system. The Arabian authors termed the one *calida*, the other *frigida*. It should be well known, however, that every acute ophthalmy, though treated in the best possible manner, is never so completely resolved, but that beyond a certain period, at which all active disturbance ceases, there yet remains in the conjunctiva, or lining of the eyelids, a degree of chronic ophthalmy, either from local weakness in the vessels, or from a morbid irritability continuing in the eye, after the cure of the acute inflammatory stage. As it occasions a diseased secretion in the organ, and a slow accumulation of blood and coagulating lymph in the part, the inexperienced are apt to suppose, that the acute ophthalmy is not yet subdued, while it is completely so. Immediately the critical moment arrives, when the acute ophthalmy changes into the chronic one, attended with local weakness, it is highly important, in the treatment, to substitute for topical emollient, relaxing applications, such as partake of an astringent, corroborant quality. Those surgeons who now continue to employ the first remedies, only protract the turgescence of the vessels, and the redness of the conjunctiva. *Quo major autem fuit inflammationis vehementia (says Richter), eo major plerumque sequitur partium affectarum atonia, eoque major opus est adstringentium et roborantium longo usu, ut auferantur penitus reliquæ morbi, &c. Fascicul. 1, p. 109, 110.*

Mild acute ophthalmy is characterized by redness of the conjunctiva and lining of the eyelids, an unnatural sensation of heat in the eyes, uneasiness, itching and shooting pains, as if sand had got between the palpebræ and eye-ball. At the place where the pain seems most severe, some blood-vessels appear more prominent and turgid, than other vessels of the same class. The patient of his own accord keeps the eyelids closed; for, he feels a weariness and restraint in opening them, and by this means, also, he moderates the action of the light, to which he cannot expose himself, without increasing the burning sensation, lancinating pain, and effusion of tears from the eye. If the constitution is

irritable, the pulse will be a little accelerated, particularly towards the evening; the skin will be dry; slight shiverings will occur, and, in some instances, nausea, and inclination to vomit. (*Scarpa.*)

This complaint is often the consequence of a cold, in which the eyes, as well as the pituitary cavities, fauces, and trachea, are affected. It is not unfrequently occasioned by change of weather, sudden transitions from heat to cold, the prevalence of easterly winds, journeys through damp, unhealthy, sandy countries, in the hot season of the year, exposure of the eyes to the vivid rays of the sun, &c. Hence, it does not seem extraordinary, that it should often make its appearance as an epidemic, and afflict persons of every age and sex. Besides the preceding remote causes of ophthalmy, authors have enumerated the suppression of some habitual evacuation, such as bleedings from the nose, or piles, the menses, &c. affections of the primæ viæ, worms, dentition, &c. However, though persons thus circumstanced, are unquestionably subject to inflammation of the eyes, it may be doubted whether they are more so than other people, and when afflicted with ophthalmy, whether the alleged causes have any share in the origin of the complaint.

The mild acute ophthalmy is in general easily cured by means of low diet, gentle purging, with small repeated doses of the antimonium tartarizatum, and after making search for any extraneous body that may have insinuated itself beneath the eyelid, repeatedly washing the eye with a warm decoction of mallow leaves, and covering it with any very soft emollient poultice, included in appropriate little bags of exceedingly fine muslin. The fluid remedy may be most conveniently applied by means of an eye-glass. Scarpa orders the antimonium tartarizatum to be taken as follows: *R. Antim. tart. gr. j. Decocti Hordei ℥iiss. Crystall. tart. ʒj. Sacchari Purif. ʒvj. Misce.* To be taken in divided doses every day. I have substituted the barley water for the decoction of dog-grass, which is certainly not essential.

With this treatment, the inflammatory stage of the mild acute ophthalmy, commonly ceases in the course of four or five days. The patient no longer complains of that oppressive sense of heat, tension, throbbing, &c. experienced at first, and he can now bear a moderate light, without such an effusion of tears as was previously occasioned. In this state, how red soever the tunica conjunctiva may appear, it is no longer affected with acute inflammation, and the ophthalmy has changed, from its acute stage, into that attended with relaxation and weakness of the vessels of the conjunctiva, and mem-

branous lining of the eyelids. Emollients are now improper; in lieu of them, astringent, corroborant collyria should be used, by means of which the relaxed vessels of the conjunctiva and eyelid will recover their original tone, and the ophthalmia be totally removed. One of the following eye-waters, which are similar in quality to those directed by Scarpa, may be employed: *Rx. Zinci Sulphatis gr. v. Aquæ Rosæ ℥iv. Misce.* Or *Rx. Cerussæ Acetatae gr. viij. Aquæ Fœniculi ℥vj. Spiritus Vini Camphorati gutt. x. Misce.* The mild ophthalmia, originating from causes which render it an epidemic, so quickly passes over the first inflammatory stage, that it is scarcely observable, and is, according to Scarpa, the only case in which cold astringent applications prove in the first instance beneficial.

Surgeons in this country certainly very often employ vitriolated collyria at first, in almost all cases of ophthalmia, and with great benefit; but, it is to be observed, that in general some days have usually elapsed before they are consulted. If the continental surgeons are accurate in their remarks, astringents must be very wrong in the first instance. Richter says;—*Quotidie observo quantum damni adferant oculis inflammatis sueta illa collyria adstringentia, quantum emolumenti emollientia.*—*Fascicul. 3, p. 101.*

The Severe Acute Ophthalmia, is attended with the same kind of symptoms as the mild, but in a more aggravated form. The sensation of heat in the eyes is burning; the constriction of the whole eye and eye-lid spasmodic; the presence of even a faint light intolerable. Sometimes the effusion of tears is continual, very copious, and blended with mucus, which is apt to make the eye-lids adhere together. Sometimes this secretion is almost suppressed, and the eyes become preternaturally dry. The sympathetic fever is considerable, with restlessness, and intolerable pain at the back part of the head. The pupil is contracted, the conjunctiva of an uniformly deep red colour. On the anterior hemisphere of the eye, among the most prominent fasciculi of vessels, may be distinguished a delicate vascular network, continued from one fasciculus to another, but, all being equally turgid with blood, and coiled as it were together, seem to form a kind of excrescence, which rises above the surface of the eye, and has a tendency to project forwards, beyond the eyelids. (*Scarpa.*)

From the immoderate action of the inflamed vessels, blood is occasionally extravasated into the cellular substance, connecting the tunica conjunctiva with the sclerotica; in consequence of which, the first of these coats, which is naturally loose, becomes enormously distended, and

elevated in front of the eye, so as to make the transparent cornea seem quite sunk, and prevent the eye from being completely shut. *Chemosis* is the term usually applied to this sort of case.

The severe acute ophthalmia commonly affects only the outer part of the eyeball; but, sometimes the interior of the eye is alone affected, or at all events, more so than the outer parts. There is little change in the external parts, the patient has immense aversion, even to the faintest light, the iris has a red appearance, the pupil is exceedingly contracted, and the aqueous humour is occasionally red and turbid. From these circumstances, Scarpa thinks it not irrational to suspect, that, in the highest pitch of internal ophthalmia, there may be an extravasation of blood in the chambers of the eye, especially betwixt the choroid and sclerotic coats. Hence, may proceed the termination of the internal ophthalmia in amaurosis, so common, when the case does not end in suppuration.

The severe acute ophthalmia requires the antiphlogistic treatment, in the most rigorous degree. Tardiness in procuring evacuations, especially of blood, too often gives the disease time to advance to the state of chemosis; or else to a condition, in which suppuration, or an extravasation of lymph within the eye, is threatened; while, in other instances, the inflammation degenerates into an obstinate chronic ophthalmia from the extreme weakness produced in the vessels of the conjunctiva. Both general and topical blood-letting should, therefore, be speedily put in execution. Leeches should be applied to the vicinity of the eyelids, especially about the inner canthus, on the vena angularis, where it joins the frontal, deep orbital, and transverse vein of the face. (*Scarpa.*)

Mr. Ware objects to leeches being put on, or very near the eyelids, as they have sometimes caused a considerable swelling of the lids, and increased, instead of lessening, the irritation. In ordinary cases, this gentleman recommends applying three in the hollow of the temple, about an inch and a half from the outer part of the orbit. There is one mode of bleeding, in cases of ophthalmia, perhaps productive of more benefit than any other, and this probably on account of its acting at once both as a general and topical evacuation; I mean opening the temporal artery. In some instances, it is true, I have seen the surgeon fail in procuring from this source a sufficient quantity of blood; but I have never seen a continuance of bleeding from the wound any longer, than the practitioner himself wished.

There is one particular mode of taking blood from the eye, which, in acute inflammations, has sometimes been very use-

ful. The visible blood-vessels on that part of the conjunctiva, which covers the inside of the eyelids, are much more numerous, than those which are observable on the white of the eye. Hence, in ophthalmy, the inflammation seems greatest on the inside of the eyelids, where the blood-vessels are often not only much increased in number, but also extremely full and turgid. Sometimes, also, the whole inside of the eyelids, particularly of the lower one, is so much enlarged, as to be constantly turned out. In both these cases great benefit has been derived from scarifying the inner surface of these parts with a lancet, by means of which a considerable quantity of blood has been removed. When the upper eyelid is very œdematous in ophthalmy, and its thickness prevents the application of remedies to the eye, a few punctures made on the outside of the lid, near its edge, will cause the discharge of a bloody water, and a very quick subsidence of the swelling. When the tumefaction of the everted eyelids is very considerable, great and speedy relief has been given, by cutting off a piece from the inside of each of them with a pair of curved scissars. (*Ware, p. 39, 40.*)

General bleeding, though copious, and assisted by the topical application of leeches, does not always prove adequate to remove the high degree of inflammation, attendant on chemosis. It is expedient to employ additional means, in order to give exit to the blood effused in the cellular substance, between the conjunctiva and sclerotica, by which the former is raised so much above the level of the cornea. Scarpa recommends, for this purpose, making a circular incision in the conjunctiva, near the margin of the cornea, with a pair of curved scissars. As a lancet, however, makes a cleaner cut than these instruments, it is perhaps preferable for the operation, and scarifications might suffice, both for the discharge of the extravasated blood, and of that distending the vessels of the conjunctiva itself. In chemosis, Mr. Ware says, there cannot be an easier or a more effectual remedy than æther. A few drops are to be poured into the palm of the hand, and diffused over it, which may be immediately done by pressing the other hand against it. The hand is then to be applied to the eye, and kept so close to it that the spirit, as it evaporates, may insinuate itself into the part affected, and act on the extravasated blood, so as to disperse it. In a few instances of chemosis, in which the swelling and inflammation have been considerable, this gentleman has found the following application of singular service: *R. Interiorum foliorum recentium Lactucæ Sisilis ℥iij. Coque cum aq. pur ℥ss. in balneo mariæ pro semihora; tunc expri-*

matur succus, et applicetur paululum ad oculos et ad palpebras sæpe in die. (Ware, p. 54.)

After general and topical bleeding, aperient medicines, of the most gentle nature, should be administered; soda phosphorata, pulp of tamarinds, cream of tartar, and magnesia vitriolata, are the most proper. When the stomach is affected, Scarpa also recommends an emetic, as being peculiarly beneficial to inflamed eyes.

When bleeding and other evacuations have been practised, the next most useful measure is the application of a blister to the nape of the neck. Scarpa observes, that the skin in this situation, and that behind the ears, sympathise more closely with the eyes than any other part of the integuments. Many practitioners, however, and among them Mr. Ware, prefer blistering the temples. The latter says: "When the leeches have fallen off, and the consequent hemorrhage has ceased, I would advise a blister of the size of half-a-crown, to be applied on the temples, directly over the orifices made by the leeches, and I have found, that the sooner the blister has followed the bleeding, the more efficacious both have proved." When the ophthalmy has been very violent, and resisted the common method, Mr. Ware adds, that the most beneficial effects have also been sometimes produced by the application of a blister large enough to cover the whole head. (*P. 43, 44.*)

At first, topical emollient applications to the eye are most beneficial; such as mallows boiled in new milk; bread and milk poultices; or the soft pulp of a baked apple; all included in fine little muslin bags. Remedies of this description should be renewed at least every two hours. The patient should be directed to observe perfect quietude, and to lie with his head in an elevated position. To keep the eyelids from adhering together, in the night-time, the sperma-ceti cerate is proper. When the ophthalmy is accompanied with a violent pain in the head, Mr. Ware recommends a strong decoction of poppy-heads to be applied as a fomentation. (*P. 51.*)

Under the preceding plan of treatment, the acute stage of severe ophthalmy commonly abates in about a week. The burning heat and darting pains in the eyes, and the febrile disturbance of the constitution subside. The patient is comparatively easy, and regains his appetite. The eyelids lose their tension and wrinkle. A discharge of thick matter takes the place of a secretion of thin serum, or of a preternaturally dry state of the eyes. These organs can now be opened, without experiencing vast irritation from a moderate light. In this state, notwithstanding

the eyes may continue red, and the conjunctiva swollen, all evacuations are to be left off, as well as the use of topical emollients, for which latter astringent, corroborant collyria are to be substituted. Scarpa recommends the following application: *R. Zinci sulphatis gr. vj. Aquæ distillatæ ℥vj. Mucil. sem. cydon. mali ℥j. Spiritus vini camphor guttas paucas. Misce et cola.* This collyrium may be injected, with a syringe, between the eye and eyelids, once every two hours; or the eye may be bathed in it, by means of an eye-cup. Such persons as cannot bear cold applications to the eye, must have the same kind of collyrium a little warmed; but as soon as the irritability is lessened, they may be used cold.

The tinctura thebaica of the old London Dispensatory proves a most efficacious remedy for the second stage of acute ophthalmia, or that connected with weak vascular action in the part affected. Two or three drops may be insinuated, between the eyelids and globe of the eye, twice a day, in common cases; but in others, attended with more sensibility, once will at first be sufficient. The late Mr. Ware, who brought this application into repute, found, that introducing two or three drops of this medicine at the inner canthus, and making them glide gradually over the eye, by gently drawing down the lower eyelid, proves equally beneficial, and less painful, than dropping them at once on the eyeball. Immediately the application is made, it commonly creates a copious flow of tears: a smarting pain, and a sense of heat in the eyes, which inconveniences, however, soon cease, and the eyes become clearer, and feel evidently improved. But notwithstanding every exaggerated assertion, unbiassed surgeons are now quite convinced, that the tinctura thebaica is only a proper application, when the inflammatory action has been previously diminished by blood-letting, aperient medicines, and blisters, and when the action of the vessels has been weakened by the continuance of the disease. Mr. Ware, in recommending it, as a most effectual application, in every species and stage of the disorder, from the most mild and recent, to the most obstinate and inveterate, (*p. 51.*) has certainly been rather too zealous. Scarpa has seen the necessity of limiting the use of the remedy in question, and he has expressly pointed out, that it is only useful, when the violence of the pain, and the aversion to light, have abated. Indeed, Mr. Ware himself acknowledged, a little before sanctioning its unlimited employment in all cases, that, in certain instances, in which the complaint is generally recent, the eyes appear shining and glossy, and feel exquisite pain from the rays of light, no relief at all

was obtained. (*P. 48, 49.*) See *Tinctura Thebaica*.

Whenever the patient can easily bear a moderate degree of light, all coverings should be removed from the eyes, except a shade of green or black silk. A brighter light should be gradually admitted every day into his chamber, so that he may become habituated, as soon as possible, to the open day-light. Nothing has a greater tendency to keep up and increase the morbid irritability of the eyes, than keeping them unnecessarily long in a dark situation, or covered with compresses and bandages. (*Scarpa.*)

There is a particular species of severe acute ophthalmia, which differs from the common, in appearing with vehement inflammation and swelling of the conjunctiva and eyelids, and being followed by an extraordinary discharge of pus from the eye. It is very common in children at the breast, and is described as attacking adults on the sudden suppression of a gonorrhœa, or on the inadvertent application of the matter of clap to the eyes. These cases must be regarded as complicated with specific morbid action, and not in the light of simple inflammation, free from any diseased principle.

The *Purulent Ophthalmia* of children produces such tumefaction of the eyelids, as almost prevents them from being separated. Should the surgeon succeed in gaining a view of the membrane lining them, it appears wrinkled, and converted into a red villous surface, somewhat like the inner coat of the rectum, when protruded in young children. (*Warner on the Human Eye, page 42.*) Sometimes in the child's fits of crying, the eyelids become everted, and continue so, until rectified by an attendant. No sooner is the first short attack of inflammation past, than there succeeds a discharge of thick yellow matter, truly surprising in quantity, partly secreted from the meibomian glands, but chiefly from that villous, fungus-like surface, into which the lining of the palpebræ seems converted. If the eyelids can be opened, the matter may be seen diffused over the whole surface of the eye, and its confinement, between the swollen eyelids and the eyeball, contributes still more to aggravate the pain, increase the inflammation, and often to induce ulcers, or specks, either over a part or the whole of the cornea. If a speedy check be not put to this distressing malady, it renders the cornea so opaque and thickened, as often to form what is termed *staphyloma*. The cornea has even been known to burst, the humours to be discharged, and the eye to sink into the orbit. The febrile symptoms are at first severe; the infant is continually fretful and restless, and a diarrhœa is not unfre-

quently concomitant. The affection of the eyes is occasionally accompanied with eruptions on the head, and with marks of a scrophulous constitution. (See *Ware*, p. 138, &c.)

The antiphlogistic treatment should be quickly opposed to the progress of the disease. The temporal arteries should be opened, or leeches applied to the temples, or neighbourhood of the eyelids, and a blister put on the nape of the neck or temples. The child should be kept in a cool room, and not covered with much clothes. If no diarrhœa should prevail, it is proper to purge with a little rhubarb or magnesia in syrup of violets.

A surgeon, however, is seldom called in before the first short inflammatory stage has ceased, and an immense discharge of matter from the eyes has commenced. Of course emollient applications must generally not be used. On the contrary, astringents and corroborants are immediately indicated, in order to restore to the vessels of the conjunctiva and eyelids their original tone, to rectify the villous and fungous appearance of the lining of the palpebræ, and thus finally to check the morbid secretion of matter. For this purpose Mr. Ware strongly recommends the *aqua camphorata* of Bates's Dispensatory: $\mathcal{R}$. Cupri sulphatis, Bol. Armen. $\bar{a}$ $\bar{a}$ $\mathfrak{z}$ iv. Camphoræ $\mathfrak{z}$ j. M. & f. pulvis, de quo projice $\mathfrak{z}$ j. in aquæ bullientis $\mathfrak{h}$ iv. amove ab igne, et subsidant scæces. Mr. Ware, in his late *Remarks on Purulent Ophthalmia*, 1808, observes, that he usually directs the *aqua camphorata*, as follows: $\mathcal{R}$. Cupri sulphatis. Bol. Armen. $\bar{a}$ $\bar{a}$ gr. viij. Camphoræ gr. ij. Misce, et affunde aquæ bullientis $\mathfrak{z}$ vij. Cum lotio sit frigida, effundatur limpidus liquor, et sæpissimè injiciatur paululum inter oculum et palpebras. This remedy possesses a very styptic quality; but it is much too strong for use before it is diluted; and the degree of its dilution must always be determined by the peculiar circumstance of each case. Mr. Ware ventures to recommend about one dram of it to be mixed with an ounce of cold clear water, as a medium or standard, to be strengthened or weakened as occasion may require. (P. 143.) The remedy must be applied by means of a small ivory or pewter syringe, the end of which is a blunt-pointed cone. The extremity of this instrument is to be placed between the edges of the eyelids, in such a manner, that the medicated liquor may be carried over the whole surface of the eye. Thus the matter will be entirely washed away, and enough of the styptic medicine left behind to interrupt and diminish the excessive discharge. According to the quantity of matter, and the rapidity with which it is secreted, the strength of the applica-

tion, and the frequency of repeating it, must be regulated. In mild recent cases, the lotion may be used once or twice a day, and rather weaker than the above proportions; but, in inveterate cases, it is necessary to apply it once or twice every hour, and to increase its styptic power in proportion; and when the complaint is somewhat relieved, the strength of the lotion may be lessened, and its application be less frequent.

"The reasons for a frequent repetition of the means just mentioned, in bad cases, are, indeed, of the most urgent nature. Until the conjunctiva is somewhat thinned, and the quantity of the discharge diminished, it is impossible to know in what state the eye is; whether it is more or less injured, totally lost, or capable of any relief. The continuance, or extinction, of the sight frequently depends on the space of a few hours: nor can we be relieved from the greatest uncertainty, in these respects, until the cornea becomes visible." (*Ware*, p. 145.)

This gentleman, with every appearance of reason, condemns the use of emollient poultices, which must have a tendency to increase the swelling and relaxation of the conjunctiva. If poultices are preferred, he particularly recommends such as possess a tonic or mild astringent property; as one made of the curds of milk, turned with alum, and an equal part of unguentum sambuci, or axungia porcini. This is to be put on cold, and frequently renewed, without omitting the use of the injection. (*Ware*, p. 147.)

When the secreted matter is glutinous, and makes the eyelids so adherent together that they cannot be opened, after being shut for any length of time, the adhesive matter must be softened with a little fresh butter mixed with warm milk, or by means of any other soft oleaginous liquor, after the poultice is taken off, and before using the lotion. (P. 147.)

If the eversion of the eyelids only occurs when the child cries, and then goes off, nothing need be done in addition to the above means. When, however, the eversion is constant, the injection must be repeated more frequently than in other cases; the eyelids put in their natural position, after its use; and an attendant directed to hold on them, with his finger, for some length of time, a compress dipped in the diluted *aqua camphorata*. (P. 148.)

In some cases, when the inside of the eyelids has been very much inflamed, the *tinctura thebaica*, insinuated between the eye and eyelids, has been useful. If after the morbid secretion is checked, any part of the cornea should be opaque, the unguentum hydrargyri nitrati, melted in a spoon, and applied accurately on the

speck, with a fine hair pencil; or Janin's ophthalmic ointment, lowered and used in the same manner; may produce a cure, if the opacity be not of too deep a kind. When the local disease seems to be kept up by a bad habit, alteratives should be exhibited, such as the *æthiops mineralis*, or small doses of calomel.

The *Purulent Ophthalmia*, arising either from suppression of gonorrhœa, or from the inadvertent conveyance of gonorrhœal matter to the eyes, is said to produce rather a swelling of the conjunctiva, than of the eyelids, which is followed by a discharge of a yellow greenish matter, similar to that of clap. The heat and pain in the eyes are considerable; an aversion to light prevails, and, in some instances, an appearance of hypopion is visible in the anterior chamber of the aqueous humour. When the complaint proceeds from the second cause, it is described as being less severe.

If it be actually true, that, in adults, a species of purulent ophthalmia does originate from the sudden suppression of a gonorrhœa, are we to consider the complaint so produced as a metastasis of the disease from the urethra to the eyes? This ophthalmia does not regularly follow the suppression of gonorrhœa; nay, it is even a rare occurrence: also, when it is decidedly known, that the purulent ophthalmia has arisen from the infection of gonorrhœa, namely, in those instances, in which the matter has been incautiously communicated to the eyes, it appears, that such an affection of these organs, so produced, is different from the one alluded to, inasmuch as it is slower in its progress, and less threatening in its aspect. Hence, there is good reason for supposing, that no metastasis takes place in this species of purulent ophthalmia, supposed to be connected with a suppressed gonorrhœa: but, we must be content with inferring that, if it really has such a cause, it originates from a sympathy, prevailing between the urethra and eyes, and, that the variation of irritability, in different people, is the reason, why it is not an invariable consequence of the sudden stoppage of a gonorrhœa.

The injection of warm oil, the introduction of a bougie into the urethra, and the application of cataplasms to the perinæum, with a view of renewing the discharge from the urethra, form the outline of the practice of those, who place implicit reliance in the suppression of gonorrhœa being the cause of the complaint. The rarity of the occurrence; the frequency of the sudden cessation of the urethral discharge; the possibility of an ophthalmia arising, as well at this particular moment, as at any other, totally independent of the other complaint; cannot fail to raise

in a discerning mind a degree of doubt, concerning the veracity of the assigned cause. Besides, admitting, that there is a sympathy, between the urethra and eyes, how are we to ascertain, whether the suppression of gonorrhœa be the cause or the effect of the ophthalmia, supposing that the one ceases, and the other commences, about the same time? Actuated by such reflections, I am induced to dissuade surgeons from adopting any means calculated to renew a discharge of matter from the urethra. When the purulent ophthalmia, in adult subjects, is decidedly occasioned by the actual contact, and infection of gonorrhœal matter, applied accidentally to the eyes, no one has recommended this unnecessary and improper practice.

The first indication, in the treatment of the disease from either cause, is to oppose the violence of the inflammation, and thus resist the destruction of the eye and opacity of the cornea. A copious quantity of blood should be taken away both topically and generally; mild laxatives should be exhibited, and a blister applied to the nape of the neck, or temples. The eyes ought to be often fomented with a decoction of white poppy-heads, and warm milk repeatedly injected beneath the eyelids. To prevent the palpebræ from becoming agglutinated together, during sleep, the sperma-ceti cerate should be smeared on the margins of the tarsi, every night.

When the heat and pain in the eyes, and febrile symptoms have subsided; when an abundant discharge of pus has commenced; all topical emollients are to be relinquished, and a collyrium of *Aq. rosæ* 3x, containing *Hydrarg. mur. gr. j.* used in their place. Scarpa states, that in the ophthalmia, originating from the inadvertent communication of the matter of gonorrhœa to the eyes, applications, in the form of ointment, such as the ung. hydrarg. the unguentum ophthalmicum of Janin, to which might be added the ung. hyd. nitrat. avail more, than fluid remedies. (*Scarpa.*)

Epidemic, Purulent, Contagious, or Egyptian Ophthalmia. The latter name has been given, in consequence of the very close resemblance, which this inflammation bears to that, which destroyed the sight of a considerable number of our soldiers in Egypt in 1801. It is very different from an ophthalmia, which, at various times, has been epidemic, in this and other countries, without any purulent discharge from the eyes, which is seldom dangerous to sight, and, in a few days, generally yields to internal antiphlogistic means, and mildly astringent applications. (*Ware on the Epidemical Purulent Ophthalmia, Note, p. 3; 1808.*)

According to Mr. Peach, the patient complains, in the first stage of the disease, of a sensation seeming to arise from sand in his eye; the vessels on the albuginea become suddenly turgid with blood, and the lower palpebræ very vascular. The cases, treated in this recent state, generally yield. But, if very active measures do not arrest the progress of the disease, the second stage appears, when the palpebræ superiores become much enlarged; the eyelids can only be opened with extreme difficulty; and then either a scalding fluid is discharged and excoriates the face, or a flux of thick yellow matter takes place. In this state, it is frequently in our power to stop the progress of the evil; but, if the most decided and active practice be not adopted, the disease reaches the third stage, in which every thing is seldom of any avail in relieving the most distressing symptoms. The cornea now too often becomes ulcerated, and the eye ruptured. (See *Edinb. Med. and Surgical Journal for January, 1807.*)

The Egyptian ophthalmia has occurred to a great extent in the Royal Military Asylum at Chelsea, and Mr. M'Gregor, the surgeon of that Institution, has favoured the public with an excellent description of the disease, and some highly interesting facts and reflections upon the subject. In the Military Asylum, the symptoms of this species of ophthalmia generally made their appearance in the following order: "A considerable degree of itching was first felt in the evening; this was succeeded by a sticking together of the eyelids, principally complained of by the patient on waking in the morning. The eyelids appeared fuller externally, than they naturally are; and on examining their internal surface, this was found inflamed. The sebaceous glands of the tarsi were considerably enlarged, and of a redder colour than usual. The caruncula lachrymalis had a similar appearance.

"In 24 or 30 hours after the appearance of the above-mentioned symptoms, a viscid mucous discharge took place from the internal surface of each eyelid, and lodged at the inner canthus, till the quantity was sufficient to be pressed over the cheek by the motions of the eye. The vessels of the tunica conjunctiva, covering the eyeball, were distended with red blood, and the tunica conjunctiva was generally so thickened, and raised, as to form an elevated border round the transparent cornea. This state was often accompanied with redness of the skin round the eye; which sometimes extended to a considerable distance, and resembled, in colour, and form, very much what takes place in the cow-pox pustule, between the 9th and 12th days after inoculation.

"When the purulent discharge was considerable, there was a swelling of the external eyelids, which often prevented the patient from opening them for several days. The discharge also frequently excoriated the cheeks as it trickled down. Exposure to light caused pain. When light was excluded, and the eye kept from motion, pain was seldom much complained of.

"These symptoms in many subsided, without much aid from medicine, in 10, 12, or 14 days; leaving the eye for a considerable time in an irritable state. In several, however, the disease continued for a much longer time, and ulceration took place on the internal surface of the eyelids, and in different parts on the eyeball. If one of those small ulcers happened to be situated on the transparent cornea, it generally, on healing, left a white speck, which, however, in the young subjects, under our care, was commonly soon removed. In some few instances, an abscess took place in the substance of the eye-ball, which, bursting externally, produced irrecoverable blindness." (P. M'Gregor in *Trans. of a Society for the Improvement of Med. and Chirurg. Knowledge, Vol. 3, p. 38—40.*)

When the local symptoms had prevailed two or three days, some febrile disturbance occurred; but, except in severe cases, it was scarcely observable.

The principal difference, between the purulent ophthalmia of infants, and that of adults, consists in the different states of the tunica conjunctiva. In the former, notwithstanding the quantity of matter, confined within the eyelids, is often profuse, the inflammation of the conjunctiva is rarely considerable, and whenever the cornea becomes impaired, it is rather owing to the lodgment of such matter on it, than to inflammation. But, in the purulent ophthalmia of adults, the discharge is always accompanied with a violent inflammation, and generally with a tumefaction of the conjunctiva, by which its membranous appearance is destroyed, and the cornea is made to seem sunk in the eye-ball. (Ware, p. 23.)

According to Mr. M'Gregor, this ophthalmia is of the same nature with that, which has raged with such violence in the army at different periods since the return of our troops from Egypt in 1800, 1801, and 1802. However, he has found, that its consequences have not been so injurious to children as to adults; for, out of the great number of children, that have been afflicted with the disease at the Military Asylum, only six have lost the sight of both eyes, and twelve the sight of one eye. (*Op. cit. P. 49.*) On the other hand, Dr. Vetch informs us, that, in the second battalion of the 52d Regt.

which consisted of somewhat more, than 700 men, 636 cases of ophthalmia were admitted into the hospital between August 1805 and August 1806; and that "of this number, fifty were dismissed with the loss of both eyes, and forty with that of one." And as Mr. M'Gregor observes, it is a melancholy fact, as appears from the returns of Chelsea and Kilmainham Hospitals, that 2317 soldiers were on the 1st of Dec. 1810, a burthen upon the public, from blindness in consequence of ophthalmia. The cases, in which only one eye was lost, are not here included.

The attacks of the disease appear to be much more frequent, severe, and obstinate, in hot sultry weather, than in cold, or temperate seasons. (*P. M'Gregor, op. cit. p. 37—p. 54, &c.*)

This gentleman also observed, that the ophthalmia was more severe and protracted in persons having red hair, or a scrophulous habit, than in others. The right eye was more frequently and violently affected, than the left. In females, the symptoms are greatly aggravated for some days previous to the catamenia; but, on this evacuation taking place, they are quickly lessened. Mr. M'Gregor further remarks, that the measles, cow-pox, and mumps, go through their course as regularly in persons affected with this species of ophthalmia, as when no other disease is present; a circumstance which, with some others, proves that the disorder is entirely local. (*P. 54—55.*)

With respect to the causes of the *Egyptian Purulent Ophthalmia*, much difference of opinion has prevailed, and, indeed, there was a time, when the disease was regarded by the majority of army surgeons, who alone had opportunities of judging of it, as not being in reality contagious, but dependent upon local epidemic causes; peculiarity of climate, &c. The late Mr. Ware even doubted the propriety of calling this ophthalmia *Egyptian*, and he contended that a disease precisely similar in its symptoms and progress had been noticed long ago in this and other countries; and that, in Egypt, several varieties of ophthalmia prevail. This celebrated oculist preferred calling the disease the *Epidemical Purulent Ophthalmia*.

That there has been long known in this country an infectious species of purulent ophthalmia cannot be doubted. The case, described by many surgeons, as proceeding from the sudden stoppage of gonorrhœa, or the inadvertent application of gonorrhœal matter to the eyes, which disorder I have already noticed, is certainly an infectious purulent ophthalmia. It is also admitted, that it resembles Egyptian Ophthalmia, by the intensity and rapidity of its symptoms; but, the latter case is strongly characterized by the quickness with which it causes, especially in adults,

opacities, or ulcerations of the cornea; the long continued irritability of the eyes after the subsidence of inflammation; but, more particularly, its very infectious, or contagious nature, by which it spreads to an extent, that has never been observed with regard to any other species of purulent ophthalmia. There have been epidemic ophthalmies, of other kinds, which have been known to affect the greater part of the population of certain districts and towns in England. The celebrated ophthalmia, which happened at Newbury in Berks, some years ago, is an instance, that must be known to every body. But, I know of no purulent inflammation of the eyes, which ever spread to a great extent in England, before the return of our troops from Egypt.

These reflections, and the observations of Mr. M'Gregor, I think, now leave no doubt of two facts; first, that this ophthalmia was brought from Egypt; and, secondly, that it is contagious, or infectious, but only capable of being communicated from one person to another by actual contact of the discharge. Mr. M'Gregor relates three cases, which prove, that the matter, after its application, produces its first effects in a very short time. I shall only cite the following example: On the 25th of October, 1809, about four o'clock P. M. Nurse Flannelly, while syringing the eyes of a boy, let some of the lotion, which had already washed the diseased eyes, pass out of the syringe into her own right eye. She felt little or no smarting at the time; but, towards nine o'clock the same evening, her right eye became red, and somewhat painful, and when she awoke next morning, her eyelids were swelled, there was a purulent discharge, pain, &c. (*Op. cit. p. 51.*)

The late Mr. Ware, though he admitted, that the infection was brought into this country from Egypt by the troops, yet, he conceived, as I think, erroneously, that the same disease also sometimes arose from the matter of gonorrhœa being applied to the eyes, and also that the same disease had been prevalent in this country before the return of the army from Egypt. He thought, however, that the infection was generally communicated by contact. Mr. Ware observes: Some of the worst cases of the purulent ophthalmia of children have happened in those, whose mothers were subject to an acrimonious discharge from the vagina at the time of parturition. Some of the worst forms of the purulent ophthalmia in adults have occurred in those, who, either shortly before the attack of the ophthalmia, or, at that very time, laboured either under a gonorrhœa, or a gleet. Mr. Ware does not mean to impute every purulent ophthalmia to such a cause; but, in the majority of adults, whom he has seen

affected, if the disorder had not been produced by the application of morbid matter, from a diseased eye, it could be traced to a connexion, between the ophthalmia, and disease of the urethra. Other causes, Mr. Ware acknowledges, may contribute to aggravate, and, perhaps, produce the disorder, and the purulent ophthalmia in Egypt has been attributed to a great number. The combined influence of heat and light, of a burning dust continually raised by the wind, and of the heavy dews of the night, may powerfully tend to excite inflammations of the eyes. Yet something more must operate in causing the malignant ophthalmia now under consideration; for, the same causes operate with equal violence in some other countries, besides Egypt, and yet do not produce the same effect; and, in this country, (continues Mr. Ware) the disorder prevailed during the last summer, to as great a degree, and upon as great a number of persons, within a small district of less than a mile, as it ever did in Egypt; and, yet, beyond this space, on either side, scarcely a person was affected with it. The disorder was certainly brought into this country by the soldiers who returned from Egypt, and was probably communicated from them to many others. Now as the action of the atmosphere alone cannot account for the spreading of the disease, &c. Mr. Ware is led to believe, that this particular disorder is only communicable by absolute contact; that is, by the application of some part of the discharge, which issues, either from the conjunctiva of an affected eye, or from some other membrane secreting a similar poison, to the conjunctiva of the eye of another person. In schools and nurseries, in consequence of children using the same basins and towels, as others who had the complaint, the disease has been communicated to nearly twenty in one academy. Hence, Mr. Ware censures the indiscriminate use of those articles, in schools, nurseries, hospitals, ships, and barracks. (P. 14, 15.)

Whoever reads the account of the Egyptian ophthalmia, as given by Mr. M'Gregor, will be convinced, that the disorder is only communicable by the application of the infectious matter to the eyes. Probably, the common mode of propagation is the inadvertent use of the same towels, or even merely touching the same articles, which have been in the hands of infected persons, who must be supposed occasionally to apply their fingers more or less to the eyelids. In this last way, the commencement of the disease may be accounted for in regiments upon their entering into barracks, which have been quitted by other infected soldiers. "Flies, in warm weather, (says Mr. M'Gregor) are seen in great numbers surrounding patients la-

bouring under ophthalmia; and I much suspect are very frequently the medium, by which the disease is communicated." (P. 54.) The matter is observed to be most infectious, when the disease is in an acute state.

There is one very unaccountable fact, connected with the subject of the causes of this ophthalmia. It is well known, that the French soldiers in Egypt suffered as much as our own troops from the affection, and great numbers of them returned to France with the disease in a chronic form. "In many (says M. Roux) the influence of their native climate has sufficed for the removal of all vestige of the disorder. On the contrary, in others, it has continued in a chronic state, either attended with the loss of one, or of both eyes; and many of our invalids remain with the affliction. But, it has not been found, that these soldiers, who returned from Egypt, have ever communicated a contagious ophthalmia, either in regiments, into which many of them have been incorporated; or in invalid houses, where others have obtained their retirement; or in the individuals belonging to the different classes of society. Such is the objection that has been made, and may always be again urged, against the opinions and observations of the English, respecting the Egyptian ophthalmia." (Roux, *Voyage faite à Londres en 1814, ou Parallèle de la Chir. Angloise, &c.* p. 49.)

The treatment, recommended by Mr. Peach, consists in bleeding the patient very largely at the commencement of the disorder. Sometimes he took away 60 ounces of blood at once, and whenever there was a disposition to relapse, the lancet was freely used again. He is also an advocate for the employment of the antiphlogistic regimen in every sense of the word. Mr. Peach occasionally found advantage derived from dropping the undulated liquor plumbi acetatis into the eye; but, upon the whole, he disapproved of fluid remedies. (See *Edinb. Med. and Surgical Journal* for January 1807.)

In the cases under Mr. M'Gregor, local applications were found most advantageous. During the inflammatory stage, however, this gentleman also had recourse to antiphlogistic means, spare diet, bleeding, neutral salts, &c. The topical treatment was as follows: Leeches were freely and repeatedly applied near the eye. But while there was much surrounding redness, instead of leeches which created too much irritation, fomentations with a weak decoction of poppy-heads, and a little brandy, were used. A weak solution of acetite of lead, and sulphate of zinc, had mostly a good effect, when applied to the eye. The vinous tincture of opium did not answer the expectations entertained of it. But, of all the remedies, the ung. hydrarg. nitrat.

was found most frequently successful. It was applied by means of a camel-hair pencil, and at first weakened with twice its quantity of lard. The red precipitate, well levigated, and mixed with simple ointment, sometimes answered when the ung. hydrarg. nitrat. failed. Well levigated verdigrease, and a quack medicine, called the golden ointment, proved also sometimes efficacious. (P. 41—43.) According to Mr. M'Gregor, blisters behind the ears, and upon the neck, are useful; but hurtful when put nearer to the eye. In cases, where the disease seems to resist antiphlogistic means, and ulceration has commenced on the external surface of the cornea, this gentleman approves of discharging the aqueous humour by a puncture, as advised by Mr. Wardrop.

When the violence of the inflammation has subsided, Mr. M'Gregor recommends the use of Bates's camphorated water, diluted with four, five, or six times its quantity of water. But, the astringent collyrium, from which he saw most good derived, was a solution of the nitrate of silver, in the proportion of half a grain to every ounce of distilled water. In some cases, it may be used stronger.

Tepid sea-water has sometimes proved serviceable in removing the relicks of the complaint. (P. 56, &c.)

Mr. Ware speaks also in favour of bleeding; but has rarely carried it to the extent, it has been in the army. In weak persons, this gentleman prefers, instead of repeating venesection, topical bleeding, either from the vein, that passes on the side of the nose, or by means of five or six leeches put on the temple. Sometimes, he thinks it better to scarify the inside of the lower eyelid, with the point of a lancet, carried along parallel to, and very near the margin of this part. Mr. Ware objects to pricking the eyelid in an infinite number of places, as very painful, and likely to increase the irritation. The lancet never need be applied more, than twice, and rarely more, than once; and, perhaps, less pain will be occasioned by making the incision with the edge, rather than the point of the lancet. After taking away blood, Mr. Ware says, a large blister on the head, or back, is often useful. Anodynes should be given, with occasional purgatives, and an antiphlogistic regimen. (*Ware on Purulent Ophthalmia*, 1808, p. 26, &c.)

Dr. Vetch, on the subject of local applications in the present disease, advises keeping the eyes continually covered with linen, dipt in some cooling lotion. In the first stage, he gives the preference to dropping the aqua sapphirina into the eye; afterwards, when the swelling of the eyelids has come on, he prefers the aqua litharg. acet. While the patient is sub-

ject to a recurrence of pain, he thinks, the injection of warm water the best application. For the purpose of lessening the swelling of the eyelids, he advises compresses, dipt in the aqua litharg. acet. to be applied with a moderately firm pressure. When the swelling and other symptoms of the second stage have subsided, Dr. Vetch recommends more astringent applications, such as the aqua lithargyri acet. Bates's camphorated water, solutions of alum, and the muriate of mercury. (See *An Account of the Ophthalmia, as it appeared in England since the return of the British Army from Egypt*, by John Vetch, M.D. 1807, p. 111.)

Mr. Ware gives the preference to the aqua camphorata, which is to be used exactly in the same way, as was described above, in speaking of the purulent ophthalmia of children. I cannot help thinking, that, if army surgeons had been careful to inject their applications under the eyelids, as advised by Mr. Ware, great benefit would have been produced. In other ways, the effect of the remedies is often lost. When the inflammation has been very great, Mr. Ware has only put four, or five grains, instead of eight, of the cuprum vitriolatum to eight ounces of water; and, while the inflammation is great, he would never advise more than eight grains to this quantity of water. He usually employs the lotion cold, especially in children; but, in some adults, in whom the general fever, and local inflammation have been considerable, he has been obliged to use it warmed. In cases of great pain and swelling, it should be very weak, less often applied, and, sometimes only warm water injected. In such circumstances, Mr. Ware also sanctions fomenting the eye with a flannel, or sponge, wet with a hot decoction of poppy-heads, or mere hot water. When the cornea threatens to burst, this gentleman approves of opening it, in order to discharge the aqueous humour, by making an incision in a place, where the scar will not obstruct vision.

Having now treated of all the principal species of acute ophthalmia, I shall finish this part of the subject with noticing Mr. Wardrop's proposal to puncture the cornea, and let out the aqueous humour in particular states of inflammation of the eyes. This gentleman remarks, that if the eye of a sheep, or ox, be squeezed in the hand, the whole cornea instantly becomes cloudy, and whenever the pressure is removed, this membrane completely regains its transparency.—From this curious phenomenon in the dead eye, it was evident, that, in the living body, the transparency of the cornea might vary according to the degree of its distention; and that, in cases of opacity of the cornea, accompanied with fulness of the eye-ball, its transparency

might be restored by the evacuation of the aqueous humour. The cornea is little sensible, and, as every body knows, its wounds are free from danger. Mr. Wardrop soon met with a case, favourable for making the experiment; the cornea was milky and opaque, and the eye-ball distended and prominent, attended with acute inflammatory symptoms. The aqueous humour was discharged by a small incision, and the operation produced not only a removal of the cloudiness of the cornea, but an abatement of the pain, and a sudden check to all the inflammatory symptoms. From the success of this case, Mr. Wardrop was led to perform the operation on others, not only with a view of diminishing the opacity of the cornea, but, also, of alleviating the inflammation. Four interesting cases are related by this gentleman, very much in favour of the practice, when the eye is severely inflamed, attended with fulness of the organ, a cloudy state of the cornea, and a turbidness of the aqueous humour. Mr. Wardrop also advises the operation, whenever there is the smallest quantity of pus, in the anterior chamber, accompanied with violent symptoms of inflammation. He thinks, that, the great and immediate relief, which the method affords, is imputable to the sudden removal of tension; and he performs the operation with a small knife, such as is used for extracting the cataract. The instrument is to be oiled, and introduced, so as to make a wound of its own breadth, at the usual place of making the incision in the extraction of the cataract. By turning the blade a little on its axis, the aqueous humour flows out. (See *Edinb. Med. and Surg. Journal*, Jan. 1807.)

Mr. Ware seems to approve of Mr. Wardrop's operation in the *epidemic, purulent, or Egyptian Ophthalmia*, when, notwithstanding general evacuations, topical bleeding, mildly astringent lotions, and a strict antiphlogistic regimen, the symptoms still continue, and, especially, if the cornea begin to lose its transparency, and a white rim appear round its circumference. Mr. Ware does not object to using a small knife, of the kind, employed in extracting the cataract; but, thinks a lancet will safely answer the purpose, or, what is better, a sharp-pointed couching needle, having a blade somewhat wider than usual, and a groove in its middle. The instrument, he advises, to be introduced about one-tenth of an inch before the connexion of the cornea with the sclerotica, and pushed gently on, parallel to the plane of the iris, until the aqueous humour make its escape. (*Ware on the Purulent Ophthalmia*, p. 41, 1808.)

Perhaps, the best mode of putting an immediate stop to the Egyptian ophthalmia,

when it prevails extensively in a regiment, which is collected together in a garrison or barracks, is to put the men actually affected, in a detached hospital, and then disperse the rest of the corps as much as possible in separate billets, and separate villages. It is a disease, which only makes great head, when persons are living together in the same building, or within the same walls, in numerous bodies, and only then in the warm season of the year. Dr. Grant, Inspector General of Hospitals to the British Army now in France, has constantly succeeded in keeping the disease from spreading to any great extent in that army, by the judicious plan of recommending infected regiments, not to be kept in barracks and garrisons, but to be dispersed and billeted in different villages and hamlets.

CHRONIC OPHTHALMY.

Unfavourable peculiarities are met with in practice, which prevent the complete cure of the second stage of acute ophthalmia, or that connected with a weak vascular action in the part affected; whence the protracted disease becomes purely chronic, and threatens the slow destruction of the eye.

These peculiarities may be chiefly referred to three causes: 1. To an increased irritability continuing in the eye after the cessation of acute inflammation. 2. To some other existing affection of the eye, or neighbouring parts, of which the chronic ophthalmia is only an effect. 3. To constitutional disease.

1. That chronic ophthalmia may depend upon a morbid irritability of the eye is evinced, not only from its resisting topical astringents and corroborants, to which the disease from simple relaxation and weakness yields, but from its being exasperated by them, and even by cold water. The patient complains of a sense of weight in the upper eyelid, and restraint in opening it; the conjunctiva has a yellowish cast, and when exposed to the damp cold air, or a brilliant light, or when the patient studies by candle-light, its vessels become injected and turgid with blood. If, in combination with such symptoms, the habit of body be weak and irritable; subject to spasms; hypochondriasis, &c. then, it is manifest, that the chronic ophthalmia is connected with a general impairment of the nervous system.

2. Besides extraneous bodies, lodged between the palpebræ and eye-ball, the inversion of the ciliæ, and hairs, growing from the caruncula lachrymalis; ulcers of the cornea; prolapsus of the iris; herpetic ulcerations of the margins of the eyelids; a morbid secretion from the meibomian glands; a diseased enlargement of the cor-

nea, or of the whole globe of the eye, &c. may occasion and maintain chronic ophthalmia. —It is only my part here to mention such remote causes; for, the particular treatment of them is described in other articles. (See *Cornea, Ulcers of; Iris, Prolapsus of; Lippitudo; Staphyloma; Hydrophthalmia; Trichiasis, &c.*)

3. The cure of the second stage of acute ophthalmia may be retarded by the prevalence of scrophula in the system; or by the small-pox affecting the eyes. Chronic ophthalmia is also sometimes a consequence of lues venerea.

When chronic ophthalmia depends upon preternatural irritability, the internal exhibition of bark with valerian is proper; animal food of easy digestion; gelatinous and farinaceous broths; wine in moderation; gentle exercise; living in salubrious and mild situations; are all severally productive of benefit. Externally, the applications should be of the sedative and corroborant kind; such as aromatic spirituous vapours (from the *spiritus ammon. comp.*) applied to the eye through a funnel, for half an hour, three or four times a day; and the eyelids and eyebrows may also be rubbed with the linimentum camphoræ.

Patients, both during the treatment and after the cure, must refrain from straining the eye, and, immediately the least uneasiness is felt, must desist from exercising it. When they write, or read, it should constantly be in a steady, uniform light, and too little, as well as too much, aggravates the disease. Having once begun to use spectacles, they should never study, or survey minute objects, without them. (*Scarpa.*)

I shall conclude the subject with a few remarks upon the cure of ophthalmia, when connected with constitutional disease.

SCROPHULOUS OPHTHALMY.

No specific being known for scrophula, the treatment, in this instance, rather consists in preventing the aggravation, than in attempting the radical cure of the complaint. Every thing debilitating is hurtful, as all evacuations; indigestible food; intense study; a sedentary life; damp marshy habitations; uncleanness; frequent transitions from heat to cold. On the other hand, observing to regulate the action of the bowels with the mildest laxatives; and the administration of bark, either alone or conjoined with the tinct. guaiaci ammoniata, do good. Alterative medicines, and especially *Æthiops mineralis*, from gr. ss. to gr. xx. in the day, taken for a few weeks uninterruptedly; aqua calcis, in broth or gruel, at first, in the dose of $\mathfrak{z}$ ij. at breakfast, and afterwards the same quantity, twice daily for a few months; together with the uniform

observance of good regimen; may tend much to abbreviate the duration of this obstinate species of the disease. (*Scarpa.*)

Mr. Ware has found, that the addition of xx to xxx gr. of the sal polychrestus of the Edinburgh Dispensatory, to each dose of bark, suffices to keep the bowels in a regular state, when there is a tendency to costiveness. In some cases, in which there was little appearance of inflammation, this gentleman found the eyelids so relaxed, and the eyes so irritable, that children would not open their eyes, even in the darkest room. In some of these relaxed cases, very beneficial effects were produced by administering internally small doses of opium, night and morning, to abate the irritability. Sea-bathing is always serviceable in scrophulous ophthalmia, and, probably the mere residence on the sea-coast, and the respiration of the sea-air, may bring about some of those advantages, which have been exclusively attributed to bathing. Friction of the body with a flesh-brush or flannel, should be employed morning and evening.

With regard to topical applications, those of a soft relaxing kind prove injurious, as also retirement into dark situations. Slightly astringent collyria; the ung. tutiæ, and the ung. hyd. nitrat. are proper when there are excoriations upon the eyelids, and when, from their occasional adhesion to each other, there is reason to suspect, that the sebaceous glands secrete an acrimonious fluid. Mr. Ware has also found that one drop of the thebaic tincture, dropped into the eye, once or twice in the course of the day, contributes greatly, both to abate the irritability and to increase the strength of the relaxed vessels. (*On Scrophulous Ophthalmia, p. 26.*) The same gentleman has occasionally mixed old verjuice with cold spring-water, at first, in the proportion of one part of the former to six of the latter, and increasing the quantity of verjuice, until sometimes there has been an equal quantity of that and water. All coverings should be removed from the eyes, except a shade of green silk, and patients should be gradually habituated to a stronger light. Good air and exercise always tend to improve scrophulous constitutions, and thus, indirectly, the disease under consideration. Scrophula often disappears spontaneously, as children approach the adult state, and, if we only have it in our power to check its progress in the early stage of life, it seems to wear itself out afterwards, and whatever local effects, it may have produced, often disappear.

As the small-pox inoculation has at present almost generally been abandoned by the faculty in favour of the vaccine disease, there seems less occasion now for detailing circumstantially a very obstinate spe-

cies of ophthalmy, induced by the former complaint. When the small-pox eruption is very abundant in the face, it causes a considerable swelling of this part of the body; the eyelids become tumefied, the eyes redden, and there ensues a discharge of a very thick adhesive matter, which agglutinates the palpebræ together; so that, if no steps be taken, the eyes will continue closed for several days in succession. The matter, confined between the eyelids and globe of the eye, being perhaps of an irritating quality, and injurious from the pressure it occasions on the surrounding parts, seems capable of exciting ulceration of the cornea, and even of irremediably destroying vision. When the pustules of the small-pox in other parts of the body have suppured, they cicatrize; but, those, which happen within the margin of the cartilage of the eyelids, are prevented from healing by the diseased secretion, which is then made from the meibomian glands, and such ulcers result, as will sometimes last for several years, and even during life, if unremedied by art. (*St. Yves sur les Mal. des Yeux*, p. 216, Edit. 12mo.) After the employment of the antiphlogistic treatment, should the disease, when treated with topical astringents and corroborants, yet baffle the efforts of the surgeon, setons in the nape of the neck, kept open for a long while, prove one of the most useful remedies. Scarpa has experienced much advantage from giving, every morning and evening, to a child, ten years old, a pill, containing one grain of calomel, one grain of the sulph. aur. antim. and four grains of cicuta in powder. It is obvious, that so potent an alterative, if ever serviceable in this case, will soon evince its efficacy; nor would it be justifiable to sport with the patient's constitution by continuing its use beyond a certain period, unless sanctioned by evident signs of its salutary effects on the disease of the eyes.

When great irritability prevails, a mixture, of three drams of the vinum antimoniales, and one dram of the tinctura thebaica, given in doses of five, or six drops, in any convenient vehicle, and, at the same time, applying externally the vapours of the spiritus ammon. comp. to the eye, constitute an excellent plan of treatment. In other cases, saturnine collyria, with a little camphorated spirit of wine, or white wine, in which a little sugar is dissolved; tinct. thebaica, Janin's ointment, &c. avail most. This treatment is also applicable to the chronic ophthalmy from measles.

When inveterate ulcers remain upon the edges of the palpebræ, the disease may then be regarded as the psorophthalmy, described by Mr. Ware, and will demand

the same method of cure. (See *Psorophthalmy*.)

VENEREAL CHRONIC OPHTHALMY.

Mr. Hunter entertained doubts, whether any inflammations of the eyes were syphilitic, and he appears to build his opinion upon two circumstances; one is, that if such cases be venereal, the disease is very different from what it is when it attacks other parts, and is attended with more pain, than venereal inflammation arising from an affection of the constitution: the second is, that he never saw these cases attended with such ulceration, as occurs when the complaint invades the mouth, throat, and tongue. (*Hunter on the Venereal*, p. 324.) In regard to the first circumstances, I can accurately state, that in several cases, reputed to have been venereal ophthalmy, which I have seen in St. Bartholomew's Hospital, the pain was by no means severe, or the chief part of the malady. The disorder seemed rather to consist in an impairment of vision, with here and there little distinct plexuses of diluted blood-vessels. If the pain should be actually more severe, than that accompanying other local symptoms of lues venerea, will not the natural sensibility of the eye satisfactorily explain this semblance of a well-marked disease deviating from its determinate character? In support of this observation, may I not remark, that the progress of a venereal bubo in the groin causes greater pain, than the formation of a node on the ulna, or tibia? As to the second reason for supposing no inflammations of the eyes are truly venereal, it cannot be considered as conclusive. Syphilis does not seem invariably to produce ulceration, in every situation, where it invades the human frame, and, in the bones, indeed, it would rather seem, in general, to give rise to a process of a directly different tendency, namely, the formation of nodes; nor does it, according to Mr. Hunter's own sentiments, produce ulceration upon mucous membranes. Scarpa says, the venereal ophthalmy is peculiar in not discovering manifest signs of inflammation, stealing on clandestinely, *without much uneasiness*. It afterwards relaxes the vessels of the conjunctiva and lining of the palpebræ, and changes the secretion of Meibomius's glands. In time it causes ulceration of the margins of the eyelids; the ciliæ fall off, and the cornea grows opaque. In the worst stage, it excites itching in the eyes, which is exasperated at night, and abates in violence towards morning, as do almost all the effects of syphilis. It never attains the state of chemosis.—(*Scarpa*.)

In the few cases, which have fallen under my own observation, the decoct. sar. sap. and hydrarg. mur. have constantly improved the condition of the eye, and, when taken, for a sufficient time, have cured the disease. I do not mean to assert, that these instances were unequivocally venereal ophthalmies, I can only say, that they were reputed to be such, and yielded to the above medicines. In some cases, mezereon, guaiacum, and mercurial frictions, might be tried; and, I believe, in all cases, the use of a collyrium, containing the oxymuriate of mercury, as Scarpa recommends, would assist the operation of internal medicines, in the cure of the disease. When the eyelids are ulcerated, the ung. hydrarg. nitrati, weakened at first by the addition of twice, or thrice its quantity of hog's lard, is the best topical application.

Some interesting observations on the ophthalmia, supposed to be venereal, may be seen in Saunders's Treatise on the Diseases of the Eye; but, having noticed these remarks in another publication, I shall avoid repeating them in the present place.

INTERMITTENT OPHTHALMY.

There is a description of ophthalmia, the symptoms of which intermit, or at least remit, at stated periods. Mr. Ware has not found bark so useful in this, as in scrophulous ophthalmia; but, he has known the oxymuriate of mercury produce the most beneficial effects, and, sometimes, he has conjoined with its internal exhibition the decoct. sars. comp. (See Ware on Intermittent Ophthalmia.)

On the subject of Ophthalmia, the reader may consult with advantage, Maître-Jean, and St. Yves sur les Mal. des Yeux. Ware on Ophthalmia, Psorophthalmia, and Purulent Eyes of new-born Children: on Scrophulous and Intermittent Ophthalmia; also Additional Remarks on Ophthalmia; and Remarks on the Purulent Ophthalmia lately epidemical in this country. There is a masterly account of Ophthalmia in Richter's Anfangsg. der Wundarzn. Band. 3. The Edinburgh Med. and Surg. Journal for January 1807, contains Mr. Peach's and Mr. Wardrop's remarks. See, also, an Account of Ophthalmia, as it appeared in England, since the return of the British Army from Egypt, by John Vetch, M. D. 1807. G. J. Beer, Lehre der Augenkrankheiten, 8vo. 2 Vols. 1792. Also His Bibliotheca Ophthalmica, 4to. Wien, 1796. But, in particular, the Observations of Scarpa, in cap. 7, of his work Sulle Principali Malattie degli Occhi, Venez. 1802, merit notice: they have been ably translated by Mr. Briggs. Consult likewise a Treatise on Several Practical Points relative to the Diseases of the Eye, by J. C. Saunders, edited by Dr. Farre, 1811. Roux, Voyage

fait en Angleterre en 1814, ou Parallèle de la Chirurgie Angloise avec la Chirurgie Française, p. 37, &c. P. M'Gregor in Trans. of a Society for the Improvement of Med. and Chirurgical Knowledge, Vol. 3, p. 30, &c. Larrey's Mémoires de Chirurgie Militaire, Tom. 1, p. 202, &c. Lassus, Pathologie Chir. T. 1, p. 48, et seq. Callisen's Systema Chirurgiæ Hodiernæ, Pars 1, p. 240, &c. Hafnia, 1798.

OSCHEOCELE. (from *οσχεον*, the scrotum, and *χηλη*, a tumour.) A hernia which has descended into the scrotum.

OSTEOSARCOMA, or **OSTEOSARCOSIS.** (from *οσλον*, a bone, and *σαρξ*, flesh.) This term signifies the change of a bone into a substance, of the consistence of flesh. Bones are sometimes converted into a soft, lardy, homogeneous substance, resembling a cancerous gland, and it is this affection, to which Boyer thinks, that the appellation ought to be confined.

Callisen seems also to regard the osteosarcosis as a disorder by which the texture of the bones is converted into a fleshy or fatty substance, accompanied with a tendency to carcinoma. (*System. Chirurgiæ Hodiernæ*, p. 204, Vol. 2, Edit. 1800.) We are to understand by osteosarcoma (says Boyer, an alteration of the osseous structure, in which, after more or less distention, the substance of the bone degenerates, and is transformed into a diversified mass, but, more or less analogous to that of cancer of the soft parts; while the local and general symptoms still more strikingly resemble those of the latter disease. (See *Traité des Mal. Chir. T. 3, P. 587.*)

According to this writer, all the bones are liable to such a disease; but, it has been more frequently observed in the bones of the face, those of the base of the skull, the long bones of the limbs, and particularly the ossa innominata, which are perhaps oftener affected, than any other bones of the body. (*Op. cit. p. 588.*)

Foreign surgeons do not appear to entertain precisely the same ideas respecting cancer, which prevail in England: at least, they apply the term to many complaints in which there are no vestiges of a carcinomatous structure, and numerous diseases of an incurable nature receive abroad very indiscriminately the name of cancer. Thus, the French surgeons have not yet distinguished the strongly marked differences between carcinoma and fungus hæmatodes. (See Roux *Parallèle de la Chir. Angloise*, &c.; and the article *Fungus Hæmatodes*.)

Fungous diseases in the antrum expand the bones of the face, make their way out, and present a frightful specimen of disease. This change of the bones, though known to have nothing to do with cancer, (See *Antrum*), is considered by Boyer as a kind of

osteosarcoma, proceeding from carcinomatous mischief in the neighbouring soft parts; and this he adduces as an example of his first species of osteosarcoma, or that arising in consequence of previous disease in other parts. In the second species, the disorder commences in the bones, and the soft parts are secondarily affected. In all cases, osteosarcoma comes on with deeply seated pain, which sometimes lasts a considerable time before any swelling is manifest. Sometimes the pain becomes more and more afflicting, and of the lancinating kind, impairing the health even before there is any change in the form of the limb. At length, the swelling takes place, occupying the whole circumference of the member. Its nature and situation are in some measure indicated by its hardness and depth. It is unequal and tuberculated, as it were. Pressure does not lessen its size, nor make the pain worse. The soft parts are still in their natural state. The tumour, however, grows more or less rapidly, and the lancinating pains become more severe. In time, the soft parts themselves inflame, and become painful. Sometimes, the skin ulcerates, and, in this very uncommon case, the sore presents a cancerous appearance. Hectic symptoms are induced, the patient gradually loses his strength, and, at length, falls a victim to the disease.

The alteration, which the structure of the bones undergoes in osteo-sarcoma, (says Boyer) deserves great attention. Most frequently, when the disease has made considerable progress, and the tumour has existed a long while, the bony texture has disappeared more or less completely; in lieu of it, an homogeneous, greyish, yellowish, lard-like substance is found, the surface of a slice of which is smooth, much like that of very hard white of egg, or old cheese, the consistence varying from that of cartilage to that of very thick bouillie. The surrounding soft parts, which have participated in the disease of the bones, are converted into a similar matter; muscles, tendons, periosteum, ligaments, vessels, cellular substance, all are confounded in the same homogeneous mass, and have undergone the same degeneration.

In some examples, the disease is less advanced: portions of the bone are then met with, whose texture and consistence are nearly natural, and which are merely somewhat enlarged. But, in proceeding towards the centre of the disease, the substance of the bone is found softened, and its consistence less than that of cartilage, still manifestly retaining, however, a fibrous texture; while, more deeply, it is converted into a lard-like substance, resembling (says Boyer) that of parts affected with carcinoma. In these tumours, cysts are often found, sometimes containing a fe-

tid ichor,—sometimes a matter like clear bouillie; and, in certain cases, a quantity of semi-transparent, tremulous, gelatinous matter is found in the middle of the lard-like substance. Boyer records an instance, in which nearly the whole humerus was changed into a gelatinous mass. (See *Leçons sur les Mal. des Os*, T. 1, Chap. 22.)

The prognosis of this disease must always be unfavourable; for, it is equally incurable, and disposed to bring on fatal consequences, whether Boyer's opinion, concerning its being cancer of the bones, be true, or not. This author notices, that, even after amputation, the complaint almost always recurs. (P. 591.) The only chance of relief, however, obviously depends upon the possibility and success of the operation. In the *Traité des Mal. Chir.* T. 3, p. 594—605, Boyer records two cases of osteosarcoma; one of the thigh; the other, of the os innominatum. The first patient was saved by amputation. Some further particulars relative to osteosarcoma may be found in *Boyer's Traité des Maladies Chirurgicales*, T. 3; *Haller's Element. Physiol.* T. 8, p. 2, pag. 5; *S. A. Kulmus, Diss. de Oxostosi Steatomatode Claviculæ: Gedan.* 1732; *S. F. Hundermark, Diss. sistens Osteosteatomatis Casum rariorem; Lips.* 1752; *S. G. Hermann, Diss. de Osteosteomate, Lips.* 1767; *S. C. Planck, de Osteosarcosi: Tub.* 1781, &c.

OZÆNA. (from *οζη*, a stench.) An ulcer situated in the nose, discharging a fetid, purulent matter, and sometimes accompanied with caries of the bones. Some authors have signified, by the term, an ill-conditioned ulcer in the antrum. The first meaning is the original one. The disease is described, as coming on with a trifling tumefaction and redness about the ala nasi, accompanied with a discharge of mucus, with which the nostril becomes obstructed. The matter gradually assumes the appearance of pus, is most copious in the morning, and is sometimes attended with sneezing, and a little bleeding. The ulceration occasionally extends round the ala nasi to the cheek, but, seldom far from the nose, the ala of which, also, it rarely destroys. The ozæna is often connected with scrophulous and venereal complaints. In the latter cases, portions of the ossa spongiosa often come away. After the complete cure of all venereal complaints, an exfoliating dead piece of bone will often keep up symptoms, similar to those of the ozæna, until it is detached. Mr. Pearson remarks, that the ozæna frequently occurs, as a symptom of the chachexia syphyloidea. It may perforate the septum nasi, destroy the ossa spongiosa, and even the ossa nasi. Such mischief is now more frequently the effect of the chachexia syphyloidea, than of lues venerea. The ozæna must not be confounded with ab-

scesses in the upper jawbone. (See *Antrum*.)

The constitutional disease, on which the ozæna generally depends, and which acts as the remote cause, must be relieved, before a cure of the local effect can be expected. The internal medicines, which may be necessary, are preparations of mercury, and antimony; sarsaparilla, elm

bark, Peruvian bark, muriated barytes, and muriate of lime. Sea-bathing may also do good, by improving the health. The best external applications are said to be, preparations of copper, zinc, arsenic, mercury, the pulvis sternutatorius, and diluted sulphuric acid. (*Pearson's Principles of Surgery, Chap. 12.*)

P.

PANA'RIS. (from *παρὰ*, near, and *οὖν*, the nail.) See *Whitlow*.

PANNUS. (from *πᾶν*, to labour.) When two, or three pterygia, of different sizes, occurred on the same eye, with their points directed towards the centre of the cornea, where they met, and covered all the surface of this transparent membrane with a dense pellicle, the ancients named the disease, *pannus*. (*Scarpa, Chap. 14.*)

PARACENTE'SIS. (from *παράκεντιναι*, to perforate.) The operation of tapping, or making an opening into the abdomen, thorax, or bladder, for the purpose of discharging the fluid confined in these parts in cases of ascites, empyema, hydrothorax, and retention of urine. Effused blood may also require an opening to be made into the chest; and so may confined air in the instance of emphysema.

TAPPING, OR PARACENTESIS ABDOMINIS.

When the swelling extends equally over the whole abdomen, the fluid is usually diffused among all the viscera, and is only circumscribed by the boundaries of the peritonæum. The water is occasionally included in different cysts, which are generally formed in one of the ovaries; and, in this case, the tumour, which is produced, is not so uniform, the fluctuation is not so distinct, as in the former instance, at least, this is the case while the disease has not made very great progress. The difference, also, in the consistence of the fluid, may render the fluctuation more, or less difficult of detection. When the water is contained in different cysts, it is frequently thick and gelatinous; but, when it is uniformly diffused all over the cavity of the peritonæum, it is generally thinner, and even quite limpid. Sometimes, a considerable number of hydatids are found floating in the fluid, discharged in cases of ascites.

Whatever may be the efficacy of digitalis, mercury, diuretics, and other evacuants, in ascites, they are rarely of any service in cases of local and encysted

dropsies. When such swellings continue to enlarge, notwithstanding the adoption of a few measures, which will presently be suggested, the sooner the fluid is evacuated, the better. It is also well known, that all efforts to produce a radical cure even of dropsies, which are not encysted, too frequently fail. I am decidedly of opinion, however, with Dr. Fothergill, that physicians would meet with much more success, in the treatment of ascites, if they were to recommend paracentesis to be done sooner, than they generally do. This operation is, for the most part, much too long delayed; and during a long space, the bowels are continually suffering, more and more, from the effect of the large quantity of fluid, which oppresses them. What ought to render the practice of early tapping more entitled to approbation, is, that the operation, when done in the situation, we shall presently advise, is perfectly free from danger, attended with very little pain, and need not interrupt the further trial of such medicines, as the physician may place confidence in. Paracentesis only becomes a serious measure, when the disease has existed for a great length of time, and the patient has been much weakened by it. Indeed, there seems much reason to suspect, that the operation should be done, as soon as the tension of the abdomen, and the fluctuation, leave no doubt, concerning the nature of the malady; especially, when the first trials, which have been made of internal remedies, seem to promise no success. Dr. Fothergill has demonstrated by facts, the advantages of this method. On the commencement of an ascites, this celebrated practitioner advised the trial of diuretics and other evacuants. He then adds, that, "if by a reasonable perseverance in this course, no considerable benefit accrues; if the viscera do not evidently appear to be obstructed, and unfit for the purposes of life; if the complaints have not been brought on by a long habitual train of intemperance, and from which there seems little hope of reclaiming the patient; if the strength and time of

life are not altogether against us; I desist from medicine, except of the cordial kind; and let the disease proceed, till the operation becomes safely practicable. When this is done, by the moderate use of the warmer diuretics, chalybeates and bitters, also the preparations of squills, in doses below that point, at which the stomach would be affected, I endeavour to prevent the abdomen from filling again." (*Med. Obs. and Inq. Vol. 4, p. 112.*) The same author remarks, with regard to encysted dropsies, that tapping sometimes effects a radical cure.

The operation should not only be performed in as early a stage of the disease as is compatible with the safety of the parts within the abdomen, it should also be repeated as soon as the quantity of fluid accumulated again is sufficient to make the puncture practicable without danger. Desault used to tap dropsical patients once a week, and, in many cases, after he had performed the operation two or three times, the disease was stopped.

The great number of times that the operation has been repeated in some individuals is surprising; for instance, forty-one times (*Med. Communications, Vol. 2.*); sixty-five times (*Mead*); one hundred times (*Callisen, Syst. Chir. Hodiernæ, Vol. 2, p. 55.*); and even one hundred and fifty-five times (*Phil. Trans. Vol. 69.*)

Whenever a considerable quantity of fluid is suddenly let out of the abdomen by tapping, the quick removal of the pressure of the water off the large blood-vessels, and viscera, may produce swooning, convulsions, and even sudden death. These consequences led the ancients to consider paracentesis as a very dangerous operation, and, when they ventured to perform it, they only let out the water gradually, and at intervals.

Dr. Mead, after considering what might occasion the bad symptoms resulting from too sudden an evacuation of a large quantity of fluid from the abdomen, was led to try what effect external pressure would have in preventing such consequences. This practitioner thought, that, in this way, he might keep up the same degree of pressure, which the fluid made on the viscera. The success, attending some trials of this plan, fully justified the opinion Dr. Mead had conceived; for, when the compression is carefully made, the whole of the water, contained in the abdomen of a dropsical patient, may be safely discharged, as quickly as the surgeon chooses. For this purpose, however, the whole abdomen must be equally compressed, the pressure increased in proportion as the evacuation takes place, and kept up in the same degree, for several days afterwards. In St. Bartholomew's Hospital, while the water is flowing out, the necessary degree

of pressure is usually made with a sheet which is put round the abdomen. Two assistants, who hold the ends of the sheet, gradually tighten it, in proportion, as the fluid is discharged. Immediately, after the operation, some folded flannel, sprinkled with spirit of wine, is laid over the whole anterior part of the belly, and covered with a broad linen roller, applied with due tightness round the body. Dr. Monro invented a particular kind of belt, for the purpose; but, though it may be well adapted to the object in view, it is, perhaps, unnecessary, as the above method seems to answer every end.

The instrument used for tapping the abdomen, is called a trocar. (*See Trocar.*)

Of this instrument there are several varieties; but, Richter and many other experienced surgeons, give a decided preference to the common trocar. Most of the modern alterations, which have been made in the construction of trocars, have only tended, says Richter, to render the employment of these instruments more difficult. There is no reason for the ordinary objection, that the common trocar cannot be introduced without considerable force. If the part, into which it is about to be passed, be made tense, very little force will be necessary, especially, if care be taken to rotate the instrument gently, as well as push it forward. Hence, all the inventions, which have originated from this supposed imperfection, are represented by Richter to be entirely useless. He condemns the trocar with a double-edged point, as a bad instrument. The proposal of Mr. Cline to make a puncture with a lancet first, and then to introduce into the opening a blunt-pointed trocar, is alleged to be superfluous. Nay—these innovations are declared to be worse than useless. A cutting instrument is liable to injure blood-vessels, and bring on a weakening degree of hemorrhage; and it is said, that the wound thus made, does not heal so readily, as that made with a common trocar. That sharp-edged instruments are attended with the inconvenience of being apt to wound enlarged veins, and produce an unpleasant degree of hemorrhage, is a truth, of which I have myself met with a convincing example. A female, who had a strong aversion to being tapped with a trocar, prevailed upon me to make the opening with a lancet. The puncture was made in the linea alba, about three inches below the navel. A stream of dark-coloured venous blood continued to run from the wound, the whole time the water was flowing out of the cannula, and did not cease until a compress was applied. The quantity of blood lost could not be less than a pint, or a pint and a half. In many cases, the loss of so much blood would

prove fatal to dropsical patients, and is what one must always feel anxious to avoid.

The most convenient position for the operation, is certainly when the patient is sitting in an arm-chair. However, weakness and other circumstances, frequently make it necessary to operate on the patient, as he lies in bed.

Until of late, the place, in which surgeons used to puncture the abdomen, in cases of ascites, was the centre of a line, drawn from the navel to the anterior superior spinous process of the ilium, and, on the left side, which was preferred, in consequence of the liver not being there. The place, for the puncture, was usually marked with ink, and was supposed to be always situated just over a part of the *linea semilunaris*, where there is no fleshy substance, nor any large blood-vessel, exposed to injury. This calculation, however, was made, without considering, that, in dropsy, the parietes of the abdomen do not yield equally in every situation. On the contrary, it is known, that the front is always more distended, than the lateral parts, and that the *recti* muscles, in particular, are sometimes very much widened. In consequence of these alterations, induced by the disease, no dependence can be put on any measurement, made with a view of ascertaining the precise situation of the *linea semilunaris*. The surgeon, who trusts to his being able to introduce the trocar exactly in this place, from any calculation of the above kind, will frequently wound a great thickness of muscle, instead of a part, where the abdominal parietes are thinnest. But, a still stronger objection is to be urged against the practice of attempting to tap in the *linea semilunaris*. Men, well acquainted with anatomy, have frequently been deceived in their reckoning, and, instead of hitting the intended line with their trocars, they have introduced these instruments through the *rectus* muscle, and wounded the *epigastric* artery. Patients have died from this error, with large extravasations of blood in the cavity of the *peritonæum*. In a dropsical person, who has been tapped, it is to be observed also, that, an effusion of blood in the abdomen will of course more readily take place, in consequence of the parts not being in the same close, compact, state, in which they are in the healthy condition.

Let every prudent practitioner, therefore, henceforth abandon the plan of tapping in the *linea semilunaris*, and, he may the more easily make up his mind to do so, as there is another place, where the operation may be done with the utmost facility and safety. The *linea alba* is now commonly preferred by the best surgeons; because, here no muscular fibres

need be wounded, the place can be hit with certainty, and no large blood-vessel can be injured. About the middle point, between the navel and pubes, is as good a situation for making the puncture, as can possibly be chosen. The surgeon should introduce the trocar in a steady, firm manner, never in an incautious, sudden way, lest parts contained in the *peritonæum* should be rashly wounded. For the same reason, immediately the point of the trocar has entered the abdomen, a thing always known at once, by the sudden cessation of resistance to its passing inward, it should be introduced no further, and its office of making a passage for the cannula is already accomplished. The surgeon, consequently, is now to take hold of the cannula with the thumb and index finger of his left hand, and gently insinuate it further into the cavity of the *peritonæum*, while, with his right hand, he is to withdraw the *stilette*. The fluid now gushes out, and regularly as it escapes, the sheet, which is round the patient's body, is to be tightened. All the water having been evacuated, a piece of flannel and a roller are to be immediately applied, as above explained, a piece of lint and soap-plaster having been previously applied to the wound.

It is not uncommon for the water suddenly to stop, long before the full quantity is discharged. Sometimes, this happens from a piece of intestine, or omentum, obstructing the cannula. This kind of stoppage may be removed by just introducing a probe or director, and holding the portion of viscus back. When the water is very viscid, the only thing we can do is to introduce a large trocar, if doing so should promise to facilitate the evacuation. Also, when *hydatids* obstruct the cannula, a larger instrument might allow them to escape. In encysted dropsies, the practitioner, of course, can only let the fluid out of those cavities which he can safely puncture.

When a dropsy of the ovary is very large, it also admits of being tapped in the *linea alba*; but, in this particular case, it is generally best to make the puncture where the swelling is most prominent. In this disease, the ovary is either converted into one large cavity, filled with fluid, or else it contains several distinct cells. The contents are sometimes exceedingly viscid. In early stages of the case, the tumour is situated towards one side of the abdomen, and seems to ascend out of the pelvis. This kind of progress at once distinguishes the disease from a common ascites, which is attended, from the first, with an equal, gradual, universal swelling of the abdomen. The cyst of the ovary, when it has attained a large size, generally adheres, in different places, to the inner sur-

face of the peritonæum, and, in this state, the whole abdomen often seems uniformly swollen, in consequence of the immense magnitude of the disease. The impairment of the health, arising from the pressure of the viscera, and interruption of their functions, and the great difficulty of breathing, produced by the pressure on the diaphragm, make it necessary to let out the fluid, and paracentesis must be done, in the way already related. The disease is often attended with an almost total stoppage of the secretion of urine. Sometimes, the urine is duly secreted, but a retention occurs, so that the use of the catheter becomes indispensable. Tapping, however, can only be regarded as a palliative measure; the water collects again, the same grievances recur, and the operation must be repeated. While an ovarian dropsy is recent, and even after it has been tapped, some attempts may be made to effect a radical cure. Blistering the surface of the abdomen, keeping up a discharge with the savine cerate, and applying a tight roller, have been known to do good. In France, the celebrated Le Dran laid open the cysts of ovarian dropsies. His patients did not die of the consequent inflammation, and the dropsy, indeed, was cured; but, there remained either a sarcomatous enlargement of the ovary, which continued to increase till death, or else incurable fistulæ, leading into the cyst, were the consequences. The large size of a wound, necessary for this purpose, the danger of inducing inflammation in so extensive a surface, as the cyst of a large ovarian dropsy, and the events of Le Dran's cases, are circumstances, on the whole, which ought to keep the practice from ever being revived.

A still more absurd plan has been attempted, viz. to cure the disease by injections, like hydroceles. I formerly saw two cases, in which port wine and water were injected by the late Mr. Ramsden of St. Bartholomew's Hospital: one patient died very soon afterwards of the inflammation, and the other perished more lingeringly from the same cause. Setons have been tried, without success.

Sometimes, though very seldom, the operation of paracentesis is necessary for giving vent to collections of air in the abdomen. Air, when confined in this manner, is generally contained in the bowels, which it inflates to an enormous size. Instances, however, are related of quantities of air being confined between the peritonæum and intestines: but, in some of these cases, it is said, that the air was known to have escaped through a small hole in some part of the intestinal canal, and, it is probable, that all the other examples were of the same kind. This disease is named *tympa-*

nites, and may render making an opening into the abdomen necessary. Notwithstanding authors generally recommend a small trocar for the purpose, there can be no doubt, that dividing the skin, and making a cautious puncture with a lancet through the linea alba, and peritonæum, would be a preferable mode of proceeding. The abdomen must also be compressed with a sheet, while the air is escaping, and, afterwards, with a roller, just as if the case were an ascites. Even when the air is contained in the bowels, if it should be enormous in quantity, occasion urgent symptoms, and cannot be got rid of in other ways, authors recommend paracentesis.

PARACENTESIS OF THE THORAX.

The necessity for this operation is indicated, when the heart, or lungs, are oppressed by any kind of fluid confined in the cavity of the chest. Every body knows, that the free and uninterrupted performance of the functions of these organs is essential to the support of life. When the action of these viscera is disturbed by the lodgment of a collection of any kind of fluid in the thorax, no internal medicines can be much depended upon for procuring relief. The only means, from which benefit can be rationally expected, is letting out the fluid, by making an opening in the parietes of the chest.

The nature of the effused fluid can make no difference, in regard to the propriety of discharging it in this manner; and, though some authors have only treated of this operation, as applicable to cases of hydrops pectoris, and empyema, it may also be of the greatest service when air is confined in the chest (see *Emphysema*;) or blood extravasated there (see *Wounds of the Thorax*;) so as to make dangerous pressure on the lungs and diaphragm.

In this place, I shall content myself with describing the best method of performing paracentesis thoracis, referring the reader to the articles just mentioned for information, concerning the particular symptoms and circumstances, which may render the operation proper, and the rest of the surgical treatment peculiar to each affection.

The safest, and most convenient situation, for making an opening into the chest, is between the sixth and seventh true ribs, on either side, as circumstances may render necessary. The surgeon should only recollect, that the two cavities of the pleura are completely distinct from each other, and have no communication whatsoever, so that, if fluid were contained on the left side of the thorax, making an opening into the right cavity would not serve for discharging the accumulated mat-

ter. The practitioner should also remember, that, when there is a fluid on both sides of the chest, paracentesis must never be done for the relief of the two collections, at the same time; because, there is great reason to believe, that, as the lungs on one side usually collapse, when there is a free communication between the air and inside of the thorax, they would do so on both sides, were an opening made at the same time into each bag of the pleura. It is hardly necessary to remark, that, in this condition, the patient could not breathe, and would die suffocated. The operation consists, in making an incision, about two inches long, through the integuments, which cover the space between the sixth and seventh true ribs, just where the indigations of the serratus major anticus muscle meet those of the externus obliquus. Here it is unnecessary to divide any muscular fibres, except those of the intercostal muscles, and, by putting the patient in a proper posture, the opening that is to be made, will be depending enough for any purpose whatsoever. The surgeon, avoiding the lower edge of the upper rib, where the intercostal artery lies, is then cautiously to divide the layers of the intercostal muscles, till he brings the pleura into view; when this membrane is to be very carefully divided with a lancet. The instrument should never be introduced in the least deeply, lest the lungs should be injured. The size of the opening in the pleura should never be larger than necessary. The discharge of blood and matter will of course require a freer aperture, than that of air, or water. If requisite, a cannula may be introduced into the wound, for the purpose of facilitating the evacuation of the fluid, and it may even in some cases, be proper to let this instrument remain in the part, in order to let the water, or pus escape, as often as another accumulation takes place. It is obvious, however, that a cannula, for this object, should only be just long enough to enter the cavity of the pleura, and should have a broad rim to keep it from slipping into the chest. A piece of sticking-plaster would easily fix the cannula, which might be stopped up with a cork, or any other convenient thing, or left open, according as the circumstances of the case, and the judgment of the surgeon, should direct.

The paracentesis of the abdomen, and that of the thorax, are described in all treatises on the operations, and systems of surgery. The works of Sharp, Le Dran, Bertrandi, Callisen, Richter, and Sabatier, are particularly deserving of attention.

For an account of the paracentesis of the bladder, refer to *Bladder, Puncture of*. Consult also *Emphysema*, *Empyema*, and *Wounds of the Thorax*.

PARAPHYMO'SIS, or **PARAPHIMO-SIS**. (from *παρά*, back, and *φίμω*, to bridle.) This signifies the case, in which the prepuce is drawn quite behind the glans penis, and cannot be brought forward again. See *Phymosis*, with which it will be considered.

PARONY'CHIA. (from *παρά*, near, and *ονυξ*, the nail.) An abscess at the end of the finger, near the nail. See *Whitlow*.

PAROTID DUCT. Every one acquainted with anatomy, is aware, that behind the jaw, on each side, there is situated a large conglomerate gland, being the principal one of such as are destined to secrete the saliva, with which the cavity of the mouth, and the food, which we swallow, are continually moistened. The parotid duct crosses the cheek, being situated about one-third from the zygoma, and two-thirds from the basis of the jaw. After passing over the masseter muscle, it pierces the buccinator, and terminates in the mouth by a considerable orifice, opposite the space, between the second and third bicuspid grinders of the upper jaw. As soon as it has passed the masseter, it dives deeply into the fat of the cheek, and, as M. Louis observes, makes an angle before it opens into the mouth. (*Mem. de l'Acad. de Chir. tom. 3, p. 457.*)

From the situation of the parotid duct, it is liable to be wounded, and this has even been done, by the surgeon's lancet, through ignorance. (See *Monro's Works, p. 520.*) In cases of this kind, the continual escape of the saliva may prevent the wound from healing, and, what is called a *salivary fistula* would be the perpetual consequence, if no steps were taken to afford relief. The parotid duct has sometimes been ruptured by blows. (*Œuvres Chir. de Desault, tom. 2, p. 221.*) Cases also occur, in which the face becomes considerably swollen, in consequence of the saliva insinuating itself into the cellular substance, just as the air does in emphysema. Respecting the last circumstance, I shall only just mention, that mischief of this kind must always be prevented from becoming very extensive, by making a depending opening for the ready escape of the fluid.

With regard to the treatment of salivary fistulæ, if the division of the parotid duct is recent, the sides of the wound should be brought into contact, and a steady pressure maintained on that part of the cheek, by means of suitable compresses, and a roller. In this manner, a salivary fistula may often be prevented altogether: either the divided ends of the duct reanite, and the spittle resumes its original course into the mouth; or, what is more probable, the wound in the face heals at every part, with the exception of a small fistulous track, which serves as a continuation of the duct

into the inside of the mouth. The latter kind of cure, however, can only take place when the wound extends quite through the cheek; but, the chance of the two portions of the duct uniting, and becoming continuous again, should always be taken in recent cases.

When a salivary fistula is actually formed, a seton, introduced from the external fistulous orifice into the mouth, is a method which seems to have, with justice, the greatest share of approbation. The celebrated *Monro* adopted this plan with success: he kept in the seton till the channel, which it had formed, had become fistulous, after which it was withdrawn, the external orifice being touched with the *argentum nitratum*, healed up, and the saliva in future flowed through the artificial fistulous channel into the mouth.

Desault used to practise the seton as follows:—He introduced two fingers of his left hand into the patient's mouth, and placing them between the teeth and the cheek, opposite the fistula, thus kept the integuments tense, and the gums from being injured. He then introduced a small hydrocele trocar, with its cannula, just before the opening of the posterior part of the duct, and pushed through the cheek, in a direction a little inclined forward. An assistant now took hold of the cannula, while *Desault* withdrew the perforator, and passed through the tube a bit of thread, into the cavity of the mouth. The cannula was next taken out, and a seton, which was then fastened to the end of the thread in the mouth, was drawn from within outward; but not so far as to come between the edges of the external opening, where the thread alone lodged, and this was fastened with sticking-plaster to the outside of the cheek. The outer wound was dressed with lint and compresses. *Desault* used to change the seton daily, introducing regularly rather a larger one, and taking especial care not to bring it between the edges of the wound, which was afterwards covered with sticking-plaster. He enjoined the patient not to move the jaw much, and only allowed him, for some time, liquid food. In about six weeks he used to omit the seton, leaving in the thread, however, for a little while longer. This being taken away, he used to finish the cure, by touching the little aperture remaining, with caustic.

The making of an artificial passage is one of the most ancient plans of curing salivary fistulæ. Every author has had his particular method of doing it, and numerous variations are to be met with, either in the instrument employed for piercing the cheek, or in the substance intended for maintaining the opening. For the first step of the operation, surgeons some-

times used the actual cautery, as *Saviard* furnishes us an instance of; sometimes an awl, as *Monro* did; sometimes a common knife, or lancet; sometimes a straight needle, which drew in the thread after it; but, *Desault's* trocar generally merits the preference, because the cannula, by remaining in the wound, after the perforator is withdrawn, allows the thread to be introduced, which in every other way, is either difficult to accomplish, or requires the use of several instruments.

For the second step of the operation, viz. keeping the opening distended, cannulæ were employed by *Duphénix*, who used to make a suture over them; a plan objectionable, inasmuch as it was attended with the inconvenience of a solid body left in the parts, and also that of the instrument being apt to slip into the mouth. The seton, therefore, ought to be preferred, and there can be no doubt that *Desault's* method is better, than the one followed by *Monro*. See on this subject, *Monro's Works*; *Œuvres Chir. de Desault, par Bichat, tom. 2, p. 221.* Also *Mém. de l'Acad. de Chir. Tom. 3.*

PARU'LIS. (from *παρεα*, near, and *ελον*, the gum.) An inflammation, boil, or abscess in the gums.

PE'NIS, AMPUTATION OF. No part of the penis should ever be amputated, on account of a mortification, because the dead portion will be naturally thrown off, and the ulcer heal, without the least occasion for putting the patient to any pain from the employment of the knife. Some cancerous, and fungous diseases, are the cases, in which it is often really proper and necessary to amputate more or less of this part of the body.

However, before a surgeon ventures to do the operation, he ought to be certain, that it is the substance of the penis, which is incurably diseased; for, as that judicious surgeon *Callisen* remarks, tumours, excrescences, ulcers, and gangrenous mischief, of the prepuce, sometimes present appearances, which may lead an inexperienced practitioner to fancy the whole thickness of the part affected with irremediable disorder, while the glans is actually in a sound state. Hence, whenever the least doubt exists, it is better to remove first the prepuce and skin, in order that the true condition of the glans may be detected. (*Callisen, Systema Chirurgiæ Hodiernæ; Pars Posterior, p. 420, Hafniæ, 1800.*)

The old surgeons, fearful of hemorrhage, used sometimes to extirpate a part of the penis, by tying ligatures round it with sufficient tightness to make it mortify and slough off. Thus, *Ruysch* removed the penis in one instance (See *Observ. 30.*) The plan, however, is exceedingly painful, and notwithstanding the authority of *Heis-*

ter, has been most properly rejected from modern surgery.

The amputation may be done in the following manner:—A circular incision is to be made through the skin, about a finger-breadth from the cancerous part. As Callisen observes, it is hardly ever requisite to draw the skin back, before it is cut; because after the corpora cavernosa are divided, they retract so considerably, that there is always a sufficiency of the integuments. (*Syst. Chir. Hodiernæ, Pars Posterior, p. 421.*) As soon therefore as the circular incision through the skin has been made, the corpora cavernosa and urethra are to be cut through, by one stroke of the knife, on a level with the cut edge of the integuments. Sabatier even advises us to draw the skin towards the glans penis, before we employ the knife, so convinced is he of the inutility of saving any of it, and of the inconveniences, which may result from its lying over and obstructing the orifice of the urethra. His mode of operating is also particularly simple, as he cuts through the integuments, and penis together by one stroke of the knife, without making any preliminary circular division of the skin. (*Médecine Opératoire, Tom. 2, p. 305, Edit. 2.*)

The bleeding arteries are now to be immediately tied: the chief are, one on the dorsum of the penis, and one in each corpus cavernosum. When a general oozing from the wound still continues, some recommend (*White, Hey, &c.*) applying sponge to its surface; others (*Latta*) finely scraped agaric, with a small proportion of pounded white sugar, or gum arabic. Perhaps, however, finely scraped lint, supported with compresses, would be quite as effectual as any styptics, and, certainly, the latter applications should be avoided, if possible, because stimulating, and productive of pain and inflammation. A surer and preferable method of stopping the oozing of blood, and at the same time of healing the wound, might be to bring the skin forward, over the end of the stump, with two strips of sticking-plaster, after introducing a flexible gum catheter into the continuation of the urethra, so as to keep its orifice unobstructed, and the urine from coming into contact with the wound. There can be little doubt, that the gum catheter would be better than a silver one, or any metallic cannula, commonly advised for the above purposes, because it lies in the passage with less irritation. It is but justice to Callisen to state, that he seems to be one of the few good surgical writers, who have particularly recommended in these cases the elastic gum catheter, in preference to that made of silver. (*Op. cit. p. 421.*) In one case, in which Mr. Hey operated, he made a longitudinal division of the integuments,

at the inferior part of the penis, so as to make them cover its extremity without puckering, or laying over the orifice of the urethra. The corpora cavernosa, however, do not readily granulate and unite to the skin by the first intention. (*Hey, p. 452.*) After the first dressings are removed, the part should be dressed with the unguentum spermatis-ceti, or any mild unirritating salve.

In consequence of the introduction of a cannula being neglected, Le Dran mentions his having seen the orifice of the urethra become closed a few hours after the operation, so that the patient could not make water. The orifice of the passage could not be discovered without great difficulty. A lancet being introduced at the point, against which the urine seemed to be forced, a quantity of it gushed out, and, as a cannula was not at hand, a sound was introduced, till one could be procured. (*Traité des Oper. de Chirurgie.*)

Pearson, in his *Practical Observations on Cancerous Complaints*, has treated of this operation: he particularly advises the skin not to be drawn back, because, when saved in this manner, it impedes the free exit of the urine. He likewise disapproves of introducing cannulæ, as creative of pain, and spasms of the urethra, and being moreover unnecessary, since the stream of urine will always preserve the urethra in a permeable state. (*P. 103.*)

Sharp, Le Dran, Bertrandi, and Sabatier's books on the operations, may be consulted. Also, *l'Encyclopédie Méthodique; Partie Chir. Art. Verge.* Hey's *Practical Observations in Surgery*, p. 445. Pearson on *Cancerous Complaints*, p. 103, &c. Warner's *Cases in Surgery*, p. 278, Edit. 4.

PENIS, CANCER OF. A wart, or a tubercle, on the prepuce, the frænum, or the glans penis, is generally the first symptom, and it often remains in a quiet state for many years. When irritated, however, it becomes painful, and enlarges, sometimes enormously, in a very short time. At the same time, ulceration, and a discharge of sanious fetid matter, take place. The disease sometimes also occasions in the urethra fistulous openings, out of which the urine escapes, and the lymphatic glands in the groin may become affected as the disease advances. Mr. Pearson says, that "cancerous excrescences have a broad base, often more extensive, than their superficies; they seem to germinate deeply from within, or rather to be a continuation of the substance of the part; and, in their progressive state, the contiguous surface has a morbid appearance." What Mr. P. considers as a venereal wart, has a basis smaller, than its surface; its roots have rather a superficial attachment, and the contiguous parts have a natural appearance, (*p. 97.*) Such are

this gentleman's marks of discrimination. We might question, however, whether Mr. Pearson, notwithstanding his great opportunities, ever saw a really *venereal* wart. For many years past I have never seen any excrescences of this kind, in St. Bartholomew's hospital, which truly required mercury for their cure, or which, when cured without it, were followed by any inconvenience. If my memory does not fail me, Mr. Abernethy also disbelieves in the doctrine of venereal warts.

Foul, spreading, sloughy ulcers of the penis, should be discriminated from cancer. It is worthy of attention, that almost all the cases of cancer of the penis recorded by Mr. Hey, were attended with a congenital phymosis. The same complication also existed in another example, in which Boyer performed amputation of the penis in la Charité on account of a cancerous affection of the part. In the only two opportunities of doing this operation, which M. Roux has had, the cases were likewise accompanied with a natural phymosis. Hence, this author considers such a state of the prepuce as particularly conducive to cancer of the penis, and earnestly enjoins surgeons to recommend their patients to have the first inconvenience rectified, so that no risk of the other more serious affection may be encountered. (See *Parallèle de la Chirurgie Anglaise*, &c. p. 306—307.) I have only seen amputation of the penis done thrice, and, in two of these cases, which were reputed to be cancerous, it did not appear, that any degree of phymosis existed. (See *Pearson on Cancerous Complaints*; *Hey's Practical Observations in Surgery*; *Roux, Voyage fait en Angleterre en 1814, ou Parallèle de la Chir. Anglaise*, &c. p. 306.)

PERINÆUM, FISTULÆ OF. See *Fistulæ in Perinæo*.

PE'RNIO (from *πτερυγία*, or *πτέρυγα*, the heel.) A chilblain, especially one on the heel. See *Chilblain*.

PESSARY. (from *πείσσω*, to soften.) The intention of pessaries, among the old practitioners, was to hold such medicinal substances, as they wished to apply within the pudenda.

Pessaries are now never made use of, except for preventing a prolapsus of the uterus, or vagina, or for keeping up a very uncommon kind of rupture, explained in the article *Hernia*.

PHAGEDÆ'NA. (from *φάγω*, to eat.) An ulcer, which spreads, and as it were eats away the flesh. Hence, the epithet, *phagedenic*, so common among surgeons.

PHARYNGOTOMY. (from *φάρυγξ*, the pharynx, and *τεμνω*, to cut.) See *Œsophagotomy*.

PHARINGO'TOMUS. (from *φάρυγξ*, the throat, and *τομή*, an incision.) An instrument for scarifying the tonsils,

and for opening abscesses about the fauces. It was invented by M. Petit, and is nothing more, than a sort of lancet, which is inclosed in a sheath. By means of a spring the point is capable of darting out to a determinate extent, so as to make the necessary wound, without risk of injuring other parts.

PHLEBO'TOMY. (from *φλεψ*, a vein, and *τεμνω*, to cut.) The operation of opening a vein, for the purpose of taking away blood. See *Bleeding*.

PHLE'GMON. (from *φλεγω*, to burn.) Healthy inflammation. See *Inflammation*.

PHLOGO'SIS. (from *φλογω*, to inflame.) An inflammation. A flushing.

PHRENI'TIS. (from *φρενις*, the diaphragm, supposed by the ancients to be the seat of the mind.) An inflammation of the brain. *Phrenzy*.

Inflammation of the brain is a frequent consequence of injuries of the head. There is an increased and disordered state of the sensibility of the whole nervous system; the retina cannot bear the usual stimulus of light; the pupils are contracted; the pulse is frequent and small; the eyes are red and turgid, perhaps in consequence of the ophthalmic artery arising from the internal carotid; the countenance is flushed, and the patient is restless, mutters incoherently, and grows wild and delirious.

Phrenitis is treated on the antiphlogistic plan. Copious bleedings, and other evacuations, are highly proper. The blood should be taken from the temporal arteries. The skin ought to be kept moist with antimonials, and a counter-irritation should be excited on the scalp by blisters.

PHY'MA. (from *φύω*, to grow.) Tubercles comprehend eight genera, and we learn from Dr. Bateman, that, under the genus *phyma*, the late Dr. Willan intended to comprise the terminthus, the epinyetis, the furunculus, and the carbuncle. (See *Bateman's Synopsis of Cutaneous Diseases*, p. 270, Edit. 3.) According to Pott, this term was formerly applied to an inflammation near the anus. See *Anus, Abscesses of*.

PHYMO'SIS, or rather **PHIMO'SIS.** (from *φίμω*, to bind up.) A disease of the penis, in which the prepuce cannot be drawn back, so as to uncover the glans. Both the phymosis, and paraphymosis, according to Mr. Hunter, arise from a thickening of the cellular membrane of the prepuce, in consequence of an irritation, capable of producing considerable and diffused inflammation. A chancre is the most frequent cause; but a mere inflammation and discharge from the glans and prepuce, and also a gonorrhœa, may bring on these affections. The inflammation often runs high, and

is frequently of the erysipelatous kind. The cellular membrane being loose, the tumefaction becomes considerable, and the end of the prepuce being a depending part, the serum often lodges in it, and makes it œdematous. A congenital contraction of the aperture of the prepuce is very common, and persons so affected, have a natural and constant phymosis. Such a state of parts (says Mr. Hunter) is often attended with chancres, and it produces very great inconveniences during the treatment. When there is considerable diffused inflammation, a diseased phymosis, similar to the natural one, unavoidably follows; and whether diseased or natural, it may produce the paraphymosis, simply by the prepuce being brought back upon the penis. This tight part, then acting as a ligature round the body of the penis, behind the glans, retards the circulation beyond the constriction, so as to produce an œdematous inflammation on the inverted part of the prepuce.

The natural or congenital phymosis is so considerable, in some children, that the urine cannot pass with ease; but, the aperture of the prepuce generally becomes larger and larger as they grow older, and the bad consequences, which the phymosis might have occasioned in disease, are thus avoided.

In some persons, especially old men, the prepuce sometimes contracts without any visible cause whatever, and becomes so narrow as to hinder the water from getting out, even after it has got free of the urethra, and, consequently, the whole cavity of the prepuce becomes filled with urine, attended with great pain.

In the phymosis, when the prepuce swells and thickens, more and more of the skin of the penis is drawn forwards over the glans, and the latter part becomes at the same time pushed backward by the swelling against its end. Mr. Hunter says, he has seen the prepuce projecting, from such a cause, more than three inches beyond the glans, and its aperture much diminished.

Mr. Hunter also notices, that the prepuce often becomes, in some degree, inverted, by the inner skin yielding more, than the outer, and the part seems to have a kind of neck, where the outer skin naturally terminates. From the tightness and distention of the parts, the prepuce now cannot be drawn more back, so as to expose any sores, which may be situated under it. This state is frequently productive of bad consequences, especially, when there are chancres behind the glans; for, the glans being between the orifice of the prepuce and the sores, the matter sometimes cannot get a passage forward, between the glans and prepuce, and, con-

sequently, it accumulates behind the corona glandis, so as to form a kind of abscess, which produces ulceration on the inside of the prepuce. This abscess bursts externally, and, the glans often protruding through the opening, the whole prepuce becomes thrown towards the opposite side, and the penis seems to have two terminations. On the other hand, (says Mr. Hunter) if the prepuce is loose and wide, and is either accustomed to be kept back in its sound state, or is pulled back to admit of the chancres being dressed, and is allowed to remain in this situation, till the above tumefaction takes place, the case is then named a *paraphymosis*. Also, when the prepuce is pulled forcibly back, after it is swelled, it is then brought from the state of a phymosis to that of a paraphymosis. The latter case is often attended with worse symptoms, than the former, especially, when it has first been a phymosis. According to Mr. Hunter, the reason of this is, that the aperture of the prepuce is naturally less elastic, than any other part of it: therefore, when the prepuce is pulled back upon the body of the penis, that part grasps it more tightly, than any other portion of the skin of the penis, and more so, according to the inflammation. Hence, there are two swellings of the prepuce, one close to the glans; the other behind the stricture. The constriction is often so great, as to interrupt the circulation beyond it. This increases the swelling, adds to the stricture, and often produces a mortification of the prepuce itself, by which means the whole diseased part, together with the stricture, is sometimes removed, forming, as Hunter ably expresses himself, a natural cure. In many cases, the skin and prepuce are not the only parts affected, adhesions, and even mortification may also take place in the glans, corpora cavernosa, &c. (See *Hunter on the Venereal*, 221, &c.)

TREATMENT OF PHYMOSIS.

A phymosis should be prevented if possible; therefore, says Mr. Hunter, upon the least signs of a thickening of the prepuce, which is known by its being retracted with difficulty and pain, the patient should be kept quiet; if in bed, so much the better, as in an horizontal position the end of the penis will not be so depending. If confinement in bed cannot be complied with, the end of the penis should be kept up, though this can hardly be done, when the patient is walking about. The object of this is to keep the extravasated fluids from gravitating to the prepuce, which they would hinder from being drawn back even more, than the inflammation itself.

As when there are sores, they cannot be dressed in the common way, injections must frequently be thrown under the prepuce, or the operation for phymosis performed. Mr. Hunter advises mercurial injections; either crude mercury rubbed down with a thick solution of gum-arabic; or calomel with the same, and a proportion of opium; or else a solution of one grain of the hydrarg. mur. in one ounce of water. Mr. Hunter also recommends the application of emollient poultices, with laudanum in them, and, before putting them on the part, to let it hang over the steam of hot water, with a little vinegar and spirits of wine in it.

When, in a case of phymosis, chancres bleed, Mr. Hunter says, the oil of turpentine is the best stimulus for making the vessels contract; but, when the hemorrhage proceeds from irritation, he recommends sedatives. Whatever is used, must be injected under the prepuce. When the inflammation has abated, he advises moving the prepuce occasionally to prevent its becoming adherent to the glans. He says, he has seen the opening of the prepuce, so much contracted from the internal ulcers healing and uniting, that there was hardly any passage for the water. If the passage in the prepuce, so contracted, be in a direct line with the orifice of the urethra, a bougie must be used. If otherwise, the operation of slitting up, or removing part of the prepuce, becomes necessary.

When matter is confined under the prepuce, in the manner above described, Mr. Hunter recommends laying the prepuce open, from the external orifice to the bottom, where the matter lies, as in a sinus, or fistula. However, Mr. Hunter thinks laying open the prepuce for the mere purpose of applying dressings unnecessary, as the sores may be washed with injections by means of a syringe.

The common operation for the phymosis consists in slitting open the prepuce, nearly its whole length in the direction of the penis. This plan is certainly the most eligible, when the matter of a chancre cannot escape from under the prepuce; because circumcision, which many surgeons, since Mr. Hunter's time, have preferred, would not suffice for giving vent to the accumulated pus. In many cases of phymosis, says Mr. Hunter, an operation is improper; for, while the inflammation is very considerable, such a measure might bring on mortification. He acknowledges, however, there are cases, in which a freedom given to the parts would prevent the latter event. When matter is confined under the prepuce, an opening is indispensable, and, if the patient should object to the common operation, an opening should be made

with a lancet directly through the prepuce, or else with a caustic. (See *Hunter on the Venereal Disease*, p. 232, et seq.)

When the prepuce is to be slit open, a director is first to be introduced under it, and the division is then to be made with a curved pointed bistoury, from within upward.

Many surgeons object to this operation, because the prepuce continues afterwards in a very deformed state; and they perform circumcision, or amputation of the prepuce, in the following manner. The prepuce is first taken hold of with a pair of forceps, as much of the part being left out, as is judged necessary to be removed. The removal is then accomplished by one sweep of the knife, which, directed by the blades of the forceps, is sure of making the incision in a straight and regular manner. A fine suture is next passed through the edges of the inner and outer portions of the skin of the prepuce, so as to keep them together. The only necessary dressings are lint, and, over it, an emollient poultice.

In nine cases, out of twelve, in which the experienced Mr. Hey has had occasion to amputate the penis for cancerous disease, the patients were also affected with a natural phymosis. (*Pract. Obs. in Surgery*.) M. Roux has noticed the same thing in three similar examples, and therefore as he conceives, that phymosis may be conducive to carcinoma of the penis, he thinks, that it should always be remedied in time. (See *Roux Parallèle de la Chir. Angloise*, p. 306.)

TREATMENT OF PARAPHYMOSIS.

The removal of the stricture in this case should always be effected, because its continuation is apt to produce a mortification in the parts, between the stricture and the glans. It may be done in two ways; either by compressing with the fingers all the blood out of the swollen glans so as to render this part sufficiently small to allow the constricting prepuce to be brought forward over it, with the aid of the two fingers; or by dividing the stricture with a knife. From the great success, which I have seen attend the first mode, I should not conceive the latter one so frequently necessary, as Mr. Hunter seems to lay down. This operation is always troublesome to accomplish, because the swelling, on each side of the stricture, covers or closes, the tight part, so as to make it difficult to get at it. Mr. Hunter says, the best way is to separate the two swellings, as much as possible, where you mean to cut, so as to expose the constricted part; then take a crooked pointed bistoury, pass it under the constriction, and divide it. None of the

swollen skin, on each side, should be cut. The prepuce may now be brought forward, unless it should be thought more convenient, for the purpose of dressing the chancres, to let it remain in its present situation. (See *Hunter on the Venereal Disease*, p. 238, 239.)

The original disease, producing phymosis and paraphymosis, must always be attended to, and the employment of mercury must be necessary, or unnecessary, according to the nature of the affection, of which these are only effects.

PILES. (See *Hemorrhoids*.)

PILULÆ AMMONIARETI CUPRI. $\mathcal{R}$. Cupri Ammoniaci gr. xvj. Micæ Panis $\mathfrak{D}$ iv. Aquæ Ammon. q. s. M. fiant pilulæ xxxii. (*Edinb. Disp.*) This is said to be the best form of exhibiting copper internally, which mineral some think worthy of trial in cases of gleets.

PILULÆ ARGENTI NITRATI. $\mathcal{R}$. Argenti Nitrati gr. iij. Aquæ Distillatæ gutt. aliquot. Micæ Panis q. s. ut fiant pil. xx. The author of the *Pharmacopœia Chirurgica* suggests the trial of these pills in obstinate leprous, and other cutaneous affections, and phagedenic, anomalous ulcers, connected with constitutional causes. Two, or three may be given twice a day. Dr. Powell gave the argentum nitratum internally, in a case of hydrophobia, but, without any sensible effect. These pills are among the *formulæ selectæ* of Dr. Saunders.

PILULÆ CALOMELANOS. $\mathcal{R}$. Calomelanos gr. xij. Conservæ Cynosbati quod satis sit. M. fiant pil. xii. These are the calomel pills in common use. Surgeons give one, or two of them daily, as alteratives, in numerous cases. At Guy's Hospital, they add three grains of the pulvis opiatuſ to each pill, using syrup, instead of the conserve.

PILULÆ CALOMELANOS CUM CICUTA. $\mathcal{R}$. Calomelanos gr. vj. Succispissati Cicutæ 3j. M. fiant pil. xii. One may be given thrice a day, in scirrhus, cancerous, scrophulous, and some anomalous diseases, resembling venereal cases.

PILULÆ CALOMELANOS CUM ANTIMONIO TARTARISATO. $\mathcal{R}$. Calomelanos 3j. Antimon. Tart. gr. xv. Opii Pur. 3ss. Syrupi simpl. q. s. fiant pil. lx. One of these is given twice a day, in St. Thomas's Hospital, in cases of diseased joints. As the author of the *Pharm. Chirurg.* adds, they are also of use in herpetic affections, and obstinate ulcers. The union of antimony with quicksilver, according to Dr. G. Fordyce, quickens the specific operation of the latter.

PILULÆ CALOMELANOS COMPOSITÆ. $\mathcal{R}$. Calomelanos. Sulph. Antim. Præcip. sing. gr. xii. Guaiaci Gummi Resinæ gr. xxiv. Saponis q. s. M. fiant

pil. xii. Similar to Plummer's pills. These are most excellent alteratives, in the dose of one twice a day. In tinea capitis, herpetic affections, and many anomalous diseases, they are exceedingly useful. Some diseased enlargements of the breast, and testicle, seem also to be benefited by them.

PILULÆ CICUTÆ. $\mathcal{R}$. Succicicutæ 3ss. Pulv. Herb. Cicutæ q. s. fiant pil. lx. These are the hemlock pills in use at Guy's Hospital. Cicuta is occasionally given in scrophulous, cancerous, and venereal cases. The surgeon should begin with small doses, and increase them gradually, till nausea and headach arise. From one, to a great number of these pills may be given, in this manner, every day.

PILULÆ CERUSSÆ ACETATÆ. $\mathcal{R}$. Cerussæ Acetatæ gr. xii. Opii Purif. gr. vj. Conserv. Cynosbati q. s. M. fiant pil. xii. One may be given thrice a day. Gleets are, perhaps, the only cases, in which surgeons can employ these pills.

PILULÆ COLOCYNTHIDIS CUM CALOMELANE. $\mathcal{R}$. Extracti Colocynth. comp. $\mathfrak{D}$ ij. Calom. gr. xii. Saponis $\mathfrak{D}$ j. Two of these operate as a purgative. They are the pills most frequently employed in the practice of surgery, for the purpose just specified.

PILULÆ CUPRI SULPHATIS. $\mathcal{R}$. Cupri Sulphatis gr. xv. Olibani Extracti Cinchonæ, sing. 3ij. Syrup. simpl. q. s. fiant pil. lx. From one to four of these pills may be given in a day, for gleets. (*Pharm. Chirurg.*)

PILULÆ HYDRARGYRI. Of these, I need only observe here, that the usual dose is ten grains. See *Mercury*.

PILULÆ HYDRARGYRI CALCINATI. One grain of this preparation is the dose, which is commonly taken at bedtime. See *Mercury*.

PILULÆ HYDRARGYRI CUM CICUTA. $\mathcal{R}$. Hydrargyri purificati drach. j. Arabici gummi pulverisati drach. ij. Succicicutæ spissati drach. j. Herbæ Cicutæ foliorum, in pulverem tritorum, q. s.

The quicksilver is to be first reduced by triture with the gum-arabic, moistened with a little rain-water. The inspissated juice of hemlock is afterwards to be added, and lastly the powdered leaves in sufficient quantity to make a suitable mass for pills.

These, with a slight variation in the proportion of the hemlock, are the *pilulæ mercuriales* of Plenck, who directs three or four pills, each of three grains, to be given every night and morning.

There are, no doubt, many cases to which this formula must be very suitable; such, for instance, as the enlarged prostate gland, &c.

Dr. Saunders in his *Formulæ Selectæ*

directs equal parts of pil. hydrarg. and succ. cicut. spissat. for these, or such like, purposes. (*Pharm. Chir.*)

PILULÆ NATRI CUM SAPONE. *Rx.* Natri 3j. Saponis ʒj. M. fiant pil. xii. Four may be given thrice a day, in cases of bronchocele, and indurations of the absorbent glands from scrophula.

PILULÆ OPII. These need only be mentioned among such as are of eminent utility in surgery.

PILULÆ OPII COMPOSITÆ. *Rx.* Opii Purif. Camphoræ, sing. ʒi. Antim. Tart. gr. xv. Syrup. Simpl. q. s. fiant pil. lx. Used for alleviating pain, and keeping up a gentle perspiration; are particularly useful in preventing painful erections, in cases of gonorrhœa, chordee, &c. (*See Pharm. Chir.*)

PILULÆ ZINCI SULPHATIS. *Rx.* Zinci Sulphatis, ʒij. Terebinthinæ q. s. fiant pil. lx. One, or two, are occasionally given, in cases of gleet, thrice a day.

PLANTARIS MUSCLE. This long slender muscle of the leg is said to be sometimes ruptured, particularly in dancing. The surgeon can do little more, than advise rest, and the same posture of the limb, as in the rupture of the tendo Achillis. (*See Achilles, Tendon of.*)

POLYPUS. (from πολυς, many, and πους, a foot.) A kind of tumour, which is generally narrow where it originates, and then becomes wider, somewhat like a pear; which is most commonly met with in the nose, uterus, vagina, and antrum; and which received its name from an erroneous idea, that it usually had several roots, or feet, like polypi, or zoophites.

POLYPUS OF THE NOSE.

Polypi more frequently grow in the cavity of the nose, from the Schneiderian membrane, than any other situation. Nasal polypi are visibly of different kinds; some being red, soft, and sensible; but, free from pain, and exactly like a piece of healthy flesh. This, which has been termed the *fleshy polypus*, is the most common, and fortunately the most easy of cure. Other polypi are called *malignant*, being hard, scirrhus, and painful: some are said to be even capable of conversion into carcinoma. Richter describes another kind of nasal polypus, which is pale, very tough, and secretes a viscid discharge; which undergoes an alteration of its size with every change of the weather; and which is rather a relaxation, or elongation, of a part of the Schneiderian membrane, than a polypous excrescence. The whole membranous lining of the nostrils is sometimes relaxed, and thickened in this manner, so as nearly to fill up all the cavity of the nose. (*Anfangsgr. der Wundarzn. Band. 1. Cap. 21.*)

Mr. Pott has taken great pains to shew, that there is one kind of polypus, originally *benign*; another originally *malignant*. He states, that those, which begin with, or are preceded by considerable, or frequent pain in the forehead and upper part of the nose, and which, as soon as they can be seen, are either highly red, or of a dark purple colour; those which, from the time of their being first noticed, have never been observed to be sometimes bigger, sometimes less, but have constantly rather increased; those, in which coughing, sneezing, or blowing the nose, gives pain, or produces a very disagreeable sensation in the nostril, or forehead; those which, when within reach, are painful to the touch, or which, upon being slightly touched, are apt to bleed; those which seem to be fixed, and not moveable by the action of blowing the nose, or of driving the air through the affected nostril only (when the polypus is only on one side); those which are incompressibly hard, and which, when pressed, occasion pain in the corner of the eye, and forehead, and which, if they shed any thing, shed blood; those which, by adhesion, occupy a very considerable space, and seem to consist of a thickening, or of an enlargement of all the membrane covering the septum narium; those which sometimes shed an ichorous, offensive, discoloured discharge; and those, round whose lower part, within the nose, a probe cannot easily and freely be passed, and that, to some height, ought not to be attempted, at least by the forceps, nor indeed by any other means; and this for reasons obviously deducible from the nature and circumstances of the polypus. On the one hand, the very large extent and quantity of adhesion will render extirpation impracticable, even if the disease could be comprehended within the forceps, which it very frequently cannot; and on the other, the malignant nature of the distemper may render all partial removal, all unsuccessful attacks on it, and indeed any degree of irritation, productive of the most disagreeable consequences.

But, the polypi, which are of a palish or greyish light-brown colour, or look like a membrane just going to be sloughy; which are seldom or never painful, nor become so upon being pressed; which have appeared to be at one time larger, at another less, as the air has happened to be moist or dry; which ascend and descend freely by the action of respiration through the nose; which the patient can make to descend by stopping the nostril which is free, or even most free, and then driving the air through that which the polypus possesses; which when pressed give no pain, easily yield to such pressure, become flat thereby, and distil

clear lymph; and round whose lower and visible part a probe can easily, and that to some height, be passed, are fair and fit for extraction; the polypus, in these circumstances, frequently coming away entire; or if it does not, yet it is removable without pain, hemorrhage, or hazard, of any kind; the second of which circumstances Mr. Pott can with strict truth affirm, he never yet met with when the disease was at all fit for the operation.

Of the benign kind of polypus, fit for extraction, there are (says Mr. Pott) two sorts, whose principal difference from each other consists in their different origin or attachment. That which is most freely moveable within the nostril, upon forcible respiration; which has been found to be most liable to change of size, at different times and seasons; which has increased the most in the same space of time; which seems most limpid, and most freely yields lymph upon pressure, has its origin most commonly by a stalk, or kind of peduncle, which is very small, compared with the size of the polypus. The other which, although plainly moveable, is much less so, than the one just mentioned, which has been less liable to alteration from air and seasons; and which has been rather slow in arriving at a very troublesome size, is most frequently an elongation of the membrane covering one of the ossa spongiosa. These latter may be extracted with no kind of hazard, and, with very little pain, and hemorrhage: but the former require the least force, and mostly come away entire; while the others often break, come away piecemeal, and stand in need of the repeated use of the forceps. (*Pott on the Polypus of the Nose.*)

Mr. John Bell criticises the distinctions drawn by the preceding writer, and he says, that a polypus is never mild, and never malignant; time, and the natural growth of the tumour, and the pressure it occasions within the soft and bony cells of the nostrils and jaws, must bring every polypus to one invariable form, in its last and fatal stage. Polypus, says Mr. John Bell, is indeed a dreadful disease; but, it becomes so by a slow progression, and advances by gradations easily characterised. Every polypus in its early stage is, according to this writer, a small moveable tumour, attended with a sneezing and watering of the eyes; swelling in moist weather; descending with the breath; but, easily repressed with the point of the finger. It is void of pain, and not at all alarming; it may also be easily extracted, so as to clear for a time the passage for the breath. Yet this little tumour, simple as it may appear, is the germ of a very fatal and loathsome disease, and this easy extraction often the very cause of its appearing in its most malignant form.

The more easily it is extracted, (says Mr. J. Bell) the more easily does it return; and whether carelessly extracted, or altogether neglected, it soon returns. But, when it does return, it has not really changed its nature; it has not ceased to be in itself mild, it is then to be feared, not from its malignity, but from its pressure, among the delicate cells and membranes of the nose. It soon fills the nostrils, obstructs the breathing, and causes indescribable anxieties. The tears are obstructed, and the eyes become watery from the pressure on the lachrymal sac; the hearing is in like manner injured, by the pressure of the tumour against the mouth of the eustachian tube; the voice is changed, and its resonance and tone entirely lost, by the sound no longer passing through the cells of the nose and face. The swallowing is in some degree affected by the soft palate being depressed by the tumour. The pains, arising from such slow and irresistible pressure, are unceasing. From the same pressure, the bones become carious, and the cells of the face and nose are destroyed by its slow growth. It is not long, before the tumour begins to project from the nostril in front, and over the arch of the palate behind. One nostril becomes widened and thickened; the nose is turned towards the opposite side of the face, and the whole countenance seems distorted. The root of the nose swells, and becomes puffy, the features tumid and flabby, the face yellow, and the parts round the eye livid. The patient is affected with head-achs, which seem to rend the bones asunder, and with perpetual stupor, and dozing. The bones are now absorbed, and the membranes ulcerate; a foul and fetid matter, blackened with blood, is discharged from the nostrils, and excoriates them. The blood-vessels next give way, and sudden impetuous hemorrhages weaken the patient; the teeth fall from the sockets, and, through the empty sockets, a foul and fetid matter issues from the antrum.

Now the disease verges to its conclusion. The patient has terrible nights, and experiences a sense of suffocation. The repeated loss of blood renders him so weak, that he cannot quit his bed, for several days together; and when he does get up, he is (to use Mr. Bell's words) pale as a spectre, his lips colourless, and his face like wax, yellow, and transparent. He now suffers intolerable pain, while his saliva is continually dribbling from his mouth, and the fetid discharge from his nose. In this state, he survives a few weeks; during the last days of his illness, lying in a state of perpetual stupor, and dying lethargic. Mr. J. Bell, afterwards, observes, that "if horrid symptoms could establish the fact of malignity, there

is not to be found in all nosology a more malignant disease, than this: but, aneurism, though it destroys the thigh-bone, the sternum, or the cranium, is not accounted malignant; neither is polypus malignant, though it destroys the cells of the face, and penetrates even through the ethmoid bone to the brain. These consequences result merely from pressure." (*John Bell's Principles of Surgery, Vol. 3, part 1, p. 90—92.*)

At the period of correcting the present article (April, 1817), a boy, in St. Bartholomew's hospital, only twelve years old, has just fallen a victim to the ravages of the largest and most disfiguring disease within the nose, which I have ever had an opportunity of beholding. The tumour before death had expanded the upper part of the nose to an enormous size, while below the left nostril was immensely enlarged. The distance between the eyes was extraordinary, being more than four inches. The left eye was affected with amaurosis, brought on by the pressure of the swelling; the right retained to the last the faculty of seeing. The tumour nearly covered the mouth, so that food could only be introduced with a spoon, and an examination of the state of the palate was impossible. About a fortnight before death, the leg became paralytic, and during the last week of the boy's existence, an incontinence of the urine and feces prevailed. On examination of the head after death, a good deal of the tumor was found to be of a cartilaginous consistence, and, what was most remarkable, a portion of it, which was as large as an orange, extended within the cranium, where it had annihilated the anterior lobe of the left hemisphere of the brain. Yet, notwithstanding this effect, the boy was not comatose, nor insensible, till a few hours before his decease. All the surrounding bones had been more or less absorbed, and the place from which the excrescence first grew, could not be determined.

The celebrated Professor Richter has also denied the validity of the objections, urged by Pott against attempting to relieve the patient: neither the malignant nature of a polypus, its adhesions, immoveableness, ulcerations, nor disposition to hemorrhage, &c. are, according to Richter, any apology for leaving the disease to itself. (*See Anfangsgr. der Wundarzn. Band. 1. Cap. 21.*)

Mr. J. Bell refutes the common notions, that polypi may be caused by picking the nose, blowing it too forcibly, colds, and local injuries. He asserts, that a polypus is not in general a local, solitary tumour: he has only found it so in three, or four instances. Both nostrils are usually affected. He states, that no finger can reach that part of the nostril, where the root of the swelling is situated, as it is deep and high

in the nostrils, towards the throat, and near the opening of the eustachian tube. The finger cannot be introduced further, than the cartilaginous wing of the nose extends, and can hardly touch the anterior point of the lower spongy bone. The anterior and posterior chambers of the nostril are separated from each other by a narrow slit, which the finger can never pass, and which is divided, in consequence of the projection of the lower spongy bone, into two openings, one above, the other below. Through these the heads of the polypus project. These tangible parts of the tumour, however, are very distant from its root, which is in the highest and narrowest part of the nostril. (*See p. 103, 104.*) Mr. J. Bell also says, that three, or four polypi are often crowded together in one nostril, while more are formed, or forming, in the other.

He dwells upon the difficulty and impracticableness of tying the root of a polypus; and explains, that in all attempts to extirpate such tumours, the surgeon's aim should be to reach a point, nearly under the socket of the eye, in the deepest and highest part of the nostrils, and that instruments can only do good when introduced beyond the narrow cleft, formed by the projection of the spongy bone. (*P. 108.*)

Though Mr. John Bell is probably right in his opinion, that polypi do not proceed from several circumstances, which we have above noticed, yet they are, in most instances, diseases of an entirely local nature. Certainly, in general, it is very difficult to describe what is the cause of the polypus nasi. Frequently the patient is, in other respects, perfectly well; and, after the removal of the tumour, no new one makes its appearance. In this circumstance, it must originate from a local cause, though it is generally difficult to define what the nature of this is. Sometimes several catarrhal symptoms precede the polypus, and, perhaps, constitute its cause. It is possible, they may only be an effect of the same cause which gives birth to the tumour; but, no doubt, they are sometimes the effect of the polypus itself. Sometimes, perhaps, a faulty state of the constitution really contributes to the disease; for, several polypi frequently grow in both nostrils, and even in other situations at the same time; are reproduced immediately after their removal; and the patient often has an unhealthy appearance. Notwithstanding it has been asserted, that a solution of the muriate of ammonia, frequently injected into the nose, sometimes disperses polypi, the efficacy of the remedy remains unestablished by experience; as, indeed, the very nature of the disease might lead one to anticipate. An operation affords the only rational chance of a cure.

There are four modes of extirpating a

nasal polypus: viz. extracting it with forceps; tying it with a ligature; cutting it out; and destroying it with caustic.

EXTRACTION.

Extraction is the most common and proper method. It is performed with the ordinary polypus forceps, the blades of which have holes in them, and are internally rather rough, in order that they may take hold of the tumour more firmly, and not easily slip off it. The front edge of each blade must not be too thin and sharp, lest, with its fellow, it should pinch off a portion of the polypus. The forceps must necessarily have a certain breadth: for, when they are too small, they cannot properly take hold of and twist the tumour. When the handles are rather long, the instrument may be more firmly closed, and more conveniently twisted.

However, the forceps are not applicable to all cases. The anterior part of the polypus, lying in the nostril, distending, and, totally obstructing it, is sometimes quite hard; and, when the forceps are introduced, it presses their blades in such a manner, from each other, as it lies between them, that the instrument cannot be introduced sufficiently far, to take hold of the tumour at a proper depth. If introduced to a proper distance, it cannot be closed. In such a case, says Richter, one might, perhaps, advantageously make use of a pair of forceps which may be separated, and put together again at the joint, and the blades of which diverge from each other behind the joint, and touch again at their extremities. After separating the two pieces, their blades are to be separately introduced, and then joined together again at the joint. The anterior indurated portion of the polypus lies in the interspace, and does not prevent the closure of the instrument.

It is generally deemed of importance to take hold of the polypus with the forceps close to its root; and, indeed, when this rule is observed, the whole of the polypus, together with its root, is commonly extracted, and there is less reason to apprehend hemorrhage, which is naturally more profuse when the polypus is broken at the thick, middle portion of its body. It is also a rule, frequently easy of observance, especially when the polypus is not too large. But, in many instances, the tumour is so large, and the nostril so completely occupied by it, that it is impracticable to get hold of its root. In this circumstance, it is often altogether impossible to discover even where the root lies. Here we must be content to take hold of the polypus as high as possible. The consequences are of two kinds. The tumour sometimes gives way at its root, though it be only taken hold of at its ante-

rior part; and, in other cases, breaks where it is grasped, a portion being left behind, and a profuse hemorrhage ensuing. This is, however, void of danger, if the surgeon loses no time in endeavouring to suppress the effusion of blood; but immediately introduces the forceps again, grasps the remnant piece, and extracts it. The most infallible method of diminishing the bleeding, is to extract what remains behind at its root. In this way, a large polypus is frequently extracted, piecemeal, without any particular loss of blood.

After the polypus has been propelled as far forward, into the nostrils, as it can be by blowing strongly through the nose, its anterior part is to be taken hold of by a small pair of common forceps, held in the left hand; and is to be drawn gradually and slowly out, to make room for the introduction of the polypus forceps into the nostril. The more slowly we proceed in this manœuvre, the more the polypus is elongated, the narrower it becomes, the greater is the space in the nostril for the introduction of the polypus forceps, and the higher can this instrument grasp the tumour. After it has taken hold of the polypus as high as possible, it is to be twisted slowly round, and, at the same time, pulled outward, till the tumour breaks. It is a very important maxim, rather to twist the instrument than to pull it, and thus, rather to writhe the polypus off, than to drag it out. The longer and more slowly the polypus forceps are twisted, the more the part where the excrescence separates, is bruised, the less is the danger of hemorrhage, and the more certainly does the tumour break at its thinnest part, or root. When the extraction is done with violence, and celerity, only a piece is usually brought away, and we run hazard of occasioning a copious bleeding.

As soon as the polypus has given way, the surgeon is to examine whether any part remains behind. When the polypus is very narrow at the place where it has been broken, and the patient can breathe through the nose freely, there is reason to presume, that the polypus has given way at its root, and that none continues behind. The finger, if it can be introduced, procures the most certain information; or the probe, when this, for want of room, cannot be employed. The ancients proposed several means for the extirpation of the remaining piece of polypus: but they are, for the most part, objectionable. It is best to introduce the forceps again, under the guidance of the finger, or probe, and thus pinch, and twist off, the part continuing behind.

Hemorrhage invariably succeeds the operation; and it has, by many, been represented as exceedingly perilous and alarming. But, it is not constantly so,

and, in many cases, is quite insignificant. Frequently, however, it is really serious; and, as the surgeon can never know beforehand to what extent it will happen, he is always to furnish himself, before the operation, with the most effectual means for its suppression. The danger of hemorrhage may always be lessened, as was before mentioned, by slowly twisting the polypus at its root, in preference to pulling it directly out. When only a portion of the tumour has been extracted, the surest mode of stopping the effusion of blood, is to extract the remaining part without delay. When the polypus has given way at its root, if there should be profuse bleeding, we may first try, ice-cold water, and strong brandy, which may either be sucked or injected into the nose. This single remedy proves effectual in numerous instances. If the hemorrhage should still prevail, it may always be checked with certainty, how copious soever, it may be, in the following manner. Roll a considerable piece of lint, as fast as possible, round the extremity of a probe; wet it completely through, with a strong solution of *zincum vitriolatum*; introduce it into the nostril, and press it as strongly as possible against the part whence the blood issues. When the nostril is very much dilated, the fingers may be used, for this purpose, with more advantage than the probe. The point, from which the blood is effused, may easily be ascertained, by asking the patient at what part of the nostril he experienced the most pain in the operation; and then pressing the finger on various points in this situation. As soon as the blood ceases to flow, we may conclude, that the finger is on the situation of the hemorrhage. This method is so efficacious, that there is seldom occasion for any other. When the bleeding point lies deeply in the nostril, it might be difficult to reach it with the finger. At all events, we may then employ the plan, which some so strongly praise in urgent cases.

A piece of cat-gut may be introduced into the nostril, and, by means of a pair of forceps, be brought out of the mouth. A roll of lint is then to be attached to it, and drawn through the mouth into the nose; thus the posterior aperture of the nostril may be stopped up. Then the nostril in front is to be filled with a sufficient quantity of lint, moistened in the solution of *zincum vitriolatum*.

The objections to extracting some polypi, says Richter, have been much exaggerated. When the polypus is so large, that its root cannot be got at, its anterior part is to be taken hold of, and the tumour extracted piecemeal. It has already been noticed, that this practice is free from danger. Experience does not prove, that the polypus, which often bleeds profusely,

is apt to occasion a violent hemorrhage in the operation; and, even if it should do so, powerful measures may be adopted for the stoppage of the bleeding. The malignity, and ulcerations, attending a polypus, are no objections to the operation; but, are rather motives for its being promptly performed, as delay must occasion more manifest and urgent danger. If the polypus should be here and there adherent to the membrane investing the nostrils, it is proper to separate it, before the operation. This object cannot be accomplished by straight inflexible instruments, such as have been invented by various surgeons. It may be very conveniently done, according to Richter, with thin, long, flat pieces of tortoise-shell, introduced as deeply as possible into the nostril, on every side of the polypus. As it can seldom be known with certainty, *à priori*, that adhesions are not present, it is proper, whenever the tumour is large, to introduce these instruments before the operation.

Sometimes, the greatest part of the polypus extends backward, hanging down behind the *palatum molle*, towards the pharynx. If there should be but little of the polypus visible in the nostril, its extraction must be performed backward, in the throat. This is usually done with a pair of curved polypus forceps, which are to be introduced through the mouth, in order to seize and tear off the tumour as high as possible above the soft palate. Care must be taken not to irritate the root of the tongue, or else a vomiting is produced, which disturbs the operation. When the polypus cannot be properly taken hold of, we may, according to the advice of some surgeons, divide the soft palate. But this is very rarely necessary. As, by this mode, the polypus is not twisted, but pulled away, the hemorrhage is, in general, rather copious. If a fragment of the tumour should remain behind, it may commonly be extracted through the nose.

Some recommend, for the extraction of polypi in the throat, a ring, consisting of two semicircular portions, with a kind of groove externally, which are capable of being opened and shut, by being fixed on the ends of an instrument constructed like forceps. A ligature is to be placed round the ring, and its end is to be brought to the handle of the instrument, and held with it in the hand. The instrument is to be introduced into the mouth, under the polypus, and expanded as much as the size of the tumour requires. Its ring is then to be carried upward, over the polypus, so as to embrace it; and afterwards is to be shut, whereby the noose after being carried upward, is disengaged from the ring. The noose is to be pushed as high as possible over the tumour, by means of forceps, and the extremity of the packthread is then to be drawn, so as to

apply the noose tightly round the polypus. When this is done, the ring of the instrument is to be turned round, firmly closed, and placed in front of the polypus, on the noose, in such a way, that the packthread is to lie between two little pegs, made for the purpose, at the ends of the ring. On drawing the packthread firmly, and pressing the instrument, at the same time, downward, so as to make it act like a lever, the polypus, in general, easily breaks. Another peg projects in the direction of the ring, so as to prevent the ligature from insinuating itself within the circle. (See *Theden's Bemerk. Part 2. and Plate 6. fig. 1. in Richter's Anfangsgr.*)

The employment of this instrument, however, is attended, says Richter, with many difficulties, and little advantage. Polypi in the throat are most conveniently extracted by the ordinary straight polypus forceps, with which they may be seized, and gradually drawn out through the mouth. The tumour generally allows itself to be drawn out without trouble, and the inclination to vomit, which at this moment occurs, also contributes to propel it outward. When it is so stretched, that it cannot be drawn out further, without considerable force, a spatula is to be introduced into the mouth, and to be carried as high as possible behind the polypus, in order to press it downward, toward the root of the tongue. When the tumour is, at the same time, forcibly pulled outward by the forceps, it usually gives way.

When the polypus is situated partly in the throat and partly in the nostril, though it admits of being extracted, in the same way, through the mouth, yet its anterior part often continues attached, and must afterwards be separately removed through the nostril. It is also frequently advisable to twist off the anterior portion of the polypus first, by which, the mass in the throat is often rendered so loose, that it can be easily extracted. Whenever it is conjectured, that the polypus will come away in two pieces, it is always preferable first, to extract the part in the nostril, and afterwards that in the throat: because, the separation of the last is constantly productive of more bleeding, than the removal of the first. Sometimes, the following plan succeeds in detaching the whole polypus at once. Both the part in the nostril, and that in the throat, are to be firmly taken hold of with the forceps, and drawn at first gently, and then more forcibly, backward and forward. By such repeated movements, the root is not unfrequently broken, and the whole polypus brought away from the mouth.

Frequently the polypus grows again. Policy requires that the patient should be apprised of this beforehand. Some of the root remaining behind, may often be a cause of the relapse. Hence, the surgeon

should examine carefully, after the operation, the part at which the root of the polypus was situated, and separate, and twist off, most diligently, with the forceps, any fragments that may still continue attached. The recurrence of the disease, however, may arise from other causes. The tumour is occasionally reproduced, after it has been extracted in the most complete manner; and, doubtless, this circumstance is sometimes owing to the continued agency of constitutional causes, which so often remain undiscovered and unremoved. Sometimes, also, the recurrence of the disease is owing to a local morbid affection of the Schneiderian membrane, or of the bones situated beneath the root of the polypus. Richter, in this case, approves of the cautery; but few English surgeons will coincide with him. The polypus, occasionally observed subsequently to the operation, is frequently not, in fact, a new substance, but only a part of the original tumour, not previously noticed by the surgeon. Sometimes it occurs, that a smaller and a larger polypus are found in the nose at the same time. The larger one is extracted, while the other remains undiscovered; and, when it has increased in magnitude, it is apt to be mistaken for a reproduction of the one previously extirpated. (See *Richter's Anfangsgr. der Wundarzn. Band. 1. Kap. 21.*)

LIGATURE.

As the extraction of the polypus is invariably attended with hemorrhage, which is sometimes profuse, another more modern method of cure has, with some, gained the preference, as being far more convenient and secure. This is, tying the root of the tumour with a ligature, by which the polypus is thrown into the state of inflammation, suppuration, and sphacelus; and, at length, becomes detached. Many instruments have been invented for applying the ligature; but Levret's double cannula seems to be the best. Through this, a silver wire is to be introduced, so as to form a noose at the upper end of the instrument, proportioned in size to the anterior part of the tumour, situated in the nostril. The two ends of the wire are to hang out of the two lower apertures of the double cannula; and one of them is to be fastened to a small ring on its own side of the instrument. The other is to remain loose. The wire must be made of the purest silver, and ought to be as flexible as possible, that it may not readily break. It must, also, not be too thin, lest it should cut through the root of the polypus. The cannula is to be somewhat less than five inches long. By the assistance of this cannula, the noose is to be introduced into the nose, and put round the polypus. But, as the cannula, which is

usually constructed of silver, is straight and inflexible, while the inner surface of the nostril is preternaturally arched, especially when much distended by the polypus, it is easy to discern that its introduction must be attended with considerable difficulty. In fact, it can seldom be introduced as deeply as the root of the polypus. There are two ways of avoiding this obstacle. The cannula may either be passed under the polypus, over the ossa palati, which present a tolerably straight surface, or it must be curved a little. Perhaps, a tortoise-shell cannula, says Richter, might be convenient.

The noose is to be applied in the following manner. The polypus is to be taken hold of with the forceps, and drawn a little out of the nose. The noose is then to be carried over the forceps and polypus, into the nostril. In order to carry it as high as possible, it is necessary not to push the cannula straight forwards into the nose, but to move it from one side of the polypus to the other. The more deeply the instrument has entered the nose, the more of the loose end of the wire must be drawn out of the lower aperture of the cannula, so as to contract the noose, which otherwise might stop in the nostril, and not be carried sufficiently high. The elasticity of the silver wire tends to assist in raising it over the polypus, and, hence, it is more easy of application than a more flaccid kind of ligature. When there is cause to conclude, that the polypus is complicated with adhesions, they must be previously broken, in the way already mentioned.

As soon as the noose has been introduced as deeply as possible, the loose extremity of the wire is to be drawn out of the lower aperture of the cannula, and rolled round the ring on that side of the instrument. Thus the root of the polypus suffers constriction. The wire must not be pulled too forcibly, nor yet too feebly. In the first circumstance, it readily cuts through the root of the polypus; in the second, great tumefaction of the excrescence, and many inconveniences arise, which a tensor state of the wire prevents. As the noose gradually makes a furrow, where it surrounds the polypus, it grows slack, after a short time, and no longer constricts the tumour. One end of the wire, therefore, is to be daily unfastened, and drawn more tightly. The more tense it is kept, the sooner the separation of the polypus is brought about. Hence, when it is particularly indicated to produce a speedy detachment of the polypus, the wire should be tightened, at least, once a day.

In this manner the cannula is to remain in the nose, until the noose is detached, together with the polypus. There is another method of tying the tumour, without leaving the cannula in the nose. After the

noose has been introduced as far as possible into the nostril, the two ends of the wire are to be twisted round the two rings, and the cannula is to be turned round a couple of times. The wire is then to be unfastened from the rings, and the cannula withdrawn. In this way, the noose is made to embrace the polypus, round which it remains fastly applied. Whenever it is wished to produce a greater constriction, the cannula may be again introduced into the nose, the ends of the wire fastened to the rings, and the instrument turned round again; after which, it is to be taken away, as before. As the cannula, when it continues long in the nose, may occasion pain, and other inconveniences, the last method seems preferable to the former. However, introducing and withdrawing the cannula every day, as Richter adds, may, perhaps, be equally troublesome and painful. The cannula, for this purpose, being necessarily straight, is by no means handy. One might, at all events, make use of a single cannula, the upper opening of which is divided by a bridge; this could be much more conveniently twisted than a double one.

Although the ligature has been very much praised by some of the moderns, it is attended with so many difficulties, that the forceps are infinitely preferable in the majority of cases. Hemorrhage is the only inconvenience, for which extraction is abandoned for the employment of the ligature. But this, as was before stated, is far less dangerous, than is represented. The inconveniences of the ligature are far more serious, and numerous. The cure by the ligature is always accomplished with much less expedition than by extraction. When the polypus is of such a size as to occupy the whole of the nostril, it is generally impracticable to introduce the noose to a sufficient depth. The figure of the polypus renders it almost impossible to tie its root; for, commonly, the tumour expands very much before and behind, and the wire must be brought over the posterior part of the polypus, ere it can be applied to its root. In general, also, the noose only includes the front part of the polypus, while the root, and back portion remain untied, and, consequently, do not become detached.—It is, indeed, asserted, that the ligature, when only applied to the front part of the polypus, is capable of bringing about inflammation, suppuration, and a detachment of the whole of the tumour. This may sometimes be the case; but, analogous instances prove, that it is undoubtedly not constantly so. The ligature seldom accomplishes an entire destruction of the disease, and there is usually reason to apprehend its recurrence. If the polypus be very large, and the whole nostril occupied, it is frequently utterly impossible to introduce

the wire ; and, when this is done, the front of the tumour alone can be tied.

The polypus nasi is commonly highly sensible, and, consequently, tying it proves very painful. As soon as the noose is drawn tight, not only the polypus inflames, but, the whole extent of the Schneiderian membrane. The pain, and inflammation, often extend even to parts at some distance, such as the throat, eyes, &c. occasioning acute fever, which requires the strict observance of low diet, the exhibition of cooling physic, and the evacuation of blood. Hence, it is advisable in many cases, to prepare patients for this treatment, by diet and medicines.

When the polypus is tied, it swells very much, and all the complaints which it previously caused are exasperated. But, in particular, the part situated in the throat, sometimes obstructs deglutition, and respiration, in such a degree, that prompt relief becomes necessary. The patient soon derives comfort, when a few punctures are made into the tumour. These excite a bleeding, that very speedily lessens the swelling, but is, sometimes, difficult to check. Hemorrhage from a part of the polypus that is tied, is most effectually stopped, by twisting the wire so tight, that it closes the arteries distributed to it.

The wire sometimes breaks off close to the lower aperture of the cannula, in consequence of being twisted so much, and thus the progress of the cure is interrupted. A new wire may be introduced ; but it is difficult to apply it exactly in the situation of the other. A fresh place is commonly tied, which is almost the same thing as commencing the cure anew. It is better to prevent this interruption of the treatment, by employing very flexible wire, made of the purest silver ; and by not twisting and untwisting regularly the same extremity of it, but sometimes one and sometimes the other. A strong piece of cat-gut might be a very good substitute for silver wire.

Immediately the polypus is tied, it swells, inflames, and becomes painful ; in a few days, it becomes shrunk, free from pain, and sphacelated. The fetid discharge now occasions considerable inconvenience to the patient, and ought to be washed away by repeated injections. Towards the termination of the case, the surgeon ought to take hold of the polypus with the forceps, to try whether any of it is loose. When the polypus is extracted, one may inject a solution of alum, for a day or two afterwards, in order to diminish the effect of the irritating discharge on the Schneiderian membrane, and the suppuration in the situation of the ligature, as it is sometimes profuse, and of long duration.

Though one might also tie polypus tumours in the throat ; and, indeed, the introduction of the cannula through the

mouth, and the application of the noose, would be attended with no great difficulty ; and, though the treatment might be rendered more tolerable to the patient, by withdrawing the cannula after twisting the wire ; yet, the swelling of the tied portion of the tumour, would, probably, create immense inconvenience. In this case, therefore, extraction usually merits the preference, and the ligature is only fit to be practised in the throat when the polypus is very small, or there is some especial cause forbidding extraction. When deglutition and respiration are impeded by the swelling of the tied portion of the polypus in the throat, the swollen part must be scarified by means of the pharyngotomus, so as to excite a bleeding, and, thereby, produce a diminution of the swelling. The noose is to be frequently and strongly tightened, in order to accelerate the detachment of the polypus, and shorten the inconveniences. When the excrescence has not only descended towards the pharynx, but also into the nostril, its front portion is to be tied first. The result of this may be, such an inflammation and suppuration of the whole polypus, that, after the separation of its anterior portion, the posterior one may also become detached, or at least, easy of removal.

CAUSTICS.

The cautery, formerly recommended for the cure of the polypus nasi, is now almost entirely rejected, and, indeed, in the manner it was customary to use it, little good could be done. It was applied to the anterior surface of the tumour in the nostril, and its employment was repeated every time the slough separated. Its operation could naturally be but of small extent, as it only came into contact with a trivial portion of polypus. Its irritation augmented the determination of blood to the excrescence, and accelerated its growth ; while as much of the tumour was reproduced, ere the slough separated, as was thus destroyed ; and the design of completely extirpating the disease, in this way, seldom or never proved successful. However, says Richter, there is one particular example, where the cautery is the only means from which relief can be derived ; and, used in a certain way, it always speedily produces the desired effect.

There are polypi of the nose, which readily bleed profusely. Touching them in the gentlest manner, and every trivial concussion of the body, give rise to hemorrhage. The patient is exceedingly debilitated by repeated loss of blood ; his countenance is pallid ; his feet swollen ; he is affected with hectic fever ; and faints whenever there is any considerable bleeding. Doubtless, extraction, in this case, is a very precarious method, as the patient

is so circumstanced, that any copious effusion of blood must be highly perilous. Sometimes the polypus is, at the same time, so large, and the nostril so completely occupied and distended, that it is impossible to apply a ligature. Such is the case, to which alone the cautery promises assistance. (*Richter.*)

In employing the cautery, (says the latter author,) the object is not to effect, by its direct agency, a gradual destruction of the polypus; but to excite such an inflammation, and suppuration, of the whole of it, as shall lead to this event. To fulfil this purpose, a common trocar, three inches long, may be used. The cannula ought to be two inches shorter than the trocar, whereby the latter may protrude from it so far; and it should be constructed with a handle. The cannula should be made wider than it is in common, to allow the trocar to be introduced, and withdrawn with facility. It is to be wrapt round with a piece of wet linen, and applied to the polypus. The red-hot trocar is then to be pushed into the tumour, as far as the cannula will allow it, which is, of course, two inches.

According to Richter, this method of treatment is far less painful than it has the semblance of being. It is only necessary to dry the front part of the nostril, and fill it with lint all round the cannula, in order that any moisture, heated during the operation, may not touch, and injure the inner surface of the nose. If care be taken to introduce the trocar in a proper direction, there is no reason to fear damaging the septum nasi, especially as it is preternaturally distended by the polypus. The immediate effect of the operation is to bring on an inflammation and swelling of the whole polypus, frequently accompanied with head-ach, sore throat, fever, and other complaints, which require the antiphlogistic treatment; but, on the whole, are not dangerous.

When the patient entertains a dread of the actual cautery, Richter sanctions the use of the potential one, in various forms. One might introduce into the puncture of the unheated trocar, a tent of the emplastrum cantharidum, or a tent smeared with butter of antimony, which may be allowed to continue in for some time. But, these applications operate slowly, and are hardly capable of exciting inflammation of the whole polypus.

As soon as suppuration has taken place, emollient and detergent lotions should be injected into the nose; cleanliness, and the promotion of the suppurative process, demand them. It is only requisite to maintain suppuration, until the polypus is so small, that it can be conveniently extracted, or tied. To effect its entire destruction by suppuration, is a tedious un-

dertaking. (*Richter's Anfangsgr.*) In England, the actual and potential cauteries are now entirely abandoned.

EXCISION.

In the treatment of the polypus, the use of cutting instruments has always been reprobated, because they usually occasion a profuse hemorrhage, and can hardly ever be passed, without mischief, to a sufficient depth into the nose to divide the root of the tumour. Yet, there are instances, in which their use might be productive of advantage. The anterior part of the polypus, situated in the nostril, is sometimes so thick and hard, that it is utterly impracticable to introduce the forceps for the performance of extraction, or the cannula for the application of the ligature. In such a case, it might be a judicious step to cut off the front of the polypus, with a sharp instrument, of a suitable shape, in order to make room for the use of the ligature, or forceps. The polypus is sometimes of a ligamentous structure, and neither admits of being tied nor extracted. There is no means of removing such a polypus, except the knife, by which it is to be cut away piecemeal.

Mr. Whately after failing in several attempts to extract, and tie, a considerable polypus of the nose, succeeded in cutting it out. He used "a narrow, straight bistoury, with a probe-point, having a sheath fixed upon its edge, by a screw put into a hole in the handle. An eye was made at its point, to receive one end of a thread intended to be passed round the polypus, for the purpose of directing the knife to the extremity of the tumour. There was also a contrivance by which the knife could be unsheathed at its extremity, the length of three quarters of an inch. This was done by means of the screw, which might be fixed in another hole, by drawing back the sheath. By exposing such a length of edge only, the interior parts of the nose were defended from the danger of being wounded." Whoever wishes a particular account of the manner of using the instrument, must consult Mr. Whately's *Cases of two extraordinary Polypi, &c.* 1805.

In the polypus, which arises from a relaxation of the Schneiderian membrane, external astringent applications may be first tried; such as ice-cold water, solutions of acetite of lead, alum, muriate of ammonia, &c. These remedies (says Richter) commonly lessen it, and frequently, when it is not very large, accomplish its entire removal. If this should not happen, there is no reason against putting a ligature round it. Here, also, we may venture to employ a cutting instrument, if it be in our power to do so. At all events, an effort may be made to bring on suppuration of the tumour, by the cautery. But,

the practice of extraction is here prohibited.

When the Schneiderian membrane is preternaturally swollen all over the nostril, which is quite obstructed, the pervious state of the cavity is to be restored by the introduction of cat-gut, or bougies. A thin piece at first passed into the nose, and afterwards a larger and larger one gradually, until the passage for the air is perfectly re-established. But, usually, this relief is only of short duration, as the nostril very soon closes again. Hence, such patients are advised to make constant use of flexible tubes passed into the nose; or, when this is too troublesome, to fill the nose regularly at bed-time, with cat-gut, and take it out again in the morning. (See *Richter's Anfangsgr. Band. 1.*)

POLYPI OF THE UTERUS.

The polypus of the uterus is of three kinds, in respect to situation. It either grows from the fundus, the inside of the cervix; or from the lower edge of the os uteri. The first case is the most frequent, the last the most uncommon. Polypi of the uterus are always shaped like a pear, and have a thin pedicle. They are almost invariably of that species, which is denominated fleshy, hardly ever being scirrhous, cancerous, or ulcerated.

The polypus of the first kind, growing from the fundus uteri, is very difficult to detect in its incipient state. While it is small, it produces not the smallest perceptible change in the organs of generation. As it enlarges, it distends the uterus, and often excites a suspicion of pregnancy, which a more attentive examination, however, soon disperses. The swelling of the abdomen does not take place in the degree and space of time, which it does in pregnancy; the menstrual discharge continues to flow; the breasts do not become full; and, in the progress of the case, no motion is to be felt. While the polypus lies in the uterus, its growth is slow. It frequently, at this early period, occasions profuse bleeding. Women afflicted with the disease, are seldom pregnant, and when they are so, parturition commonly happens prematurely. However, it occasionally occurs, that they hold out till the end of the regular time, and experience an easy and safe delivery.

As the polypus increases, it expands the os uteri, and, at length, protrudes into the vagina. This either takes place suddenly from an accidental concussion of the body; or slowly and gradually. In the latter circumstance, pains similar to those of labour occur, and cause the tumour to be expelled into the vagina. As soon as it has arrived in this situation, and is no longer confined and compressed by the

uterus, it begins to grow more rapidly, and gives rise to far more troublesome complaints. It presses the bladder and rectum, and thus, more or less, disturbs the evacuation of the urine and feces. But, in particular, it causes repeated and profuse hemorrhages, which weaken the patient exceedingly, and often bring her to the brink of the grave. The root of the polypus is situated in the os uteri, and is there so compressed, that the blood in the polypus is prevented from returning through the veins; consequently, all the vessels become turgid, and the above effusions of blood are the result. Though they generally cease spontaneously, the least circumstances cause their recurrence; such as slight concussions of the body in riding, walking, &c. In the mean while, a quantity of mucous and aqueous fluid is voided, by which the patient's strength is more reduced. The polypus, the source of this blood and mucus, is frequently misunderstood, and the patient is in a perilous state. So necessary is it in cases of preternatural discharge from the uterus, always to examine with the finger, *per vaginam*.

When the polypus has been for some time in the vagina, it at length protrudes from it externally. This happens gradually or suddenly, on the occurrence of any concussions of the body. Hence, it again excites additional grievances. As it cannot descend so low, without dragging the fundus of the uterus downward with it, and occasioning its prolapsus, the patient, on walking, or standing, commonly experiences a very painful sense of dragging, or stretching, in the pelvis. As the bladder and ureters are also forced into a deranged position, the evacuation of urine is, more or less, disturbed, or rendered difficult. The flow of the urine over the polypus, as well as the irritation of outward friction on it, frequently causes it to inflame, become painful, and ulcerated.

The polypus situated in the vagina, or protruding from it externally, may easily be mistaken for a prolapsus uteri: an error that may have very perilous consequences; but, by a careful examination, is generally not difficult to avoid. The polypus is softer and less sensible, than the uterus in the state of a prolapsus. The imperfect prolapsus uteri, in which this viscus is not turned inside out, is betrayed by the os tinæ, at the lower part of which it is plainly perceptible. In this situation, the polypus may occasionally have a depression, resembling the mouth of the womb, but easy of discrimination from it. A probe can be passed deeply into the os uteri; but, not so into this other opening. The polypus resembles an inverted pear, that is, it is thickest below, and becomes gradually thinner upward. The above species of the prolapsus uteri,

is thinnest below, and gradually increases in width upward. The fallen uterus may easily be pressed back, and when it is so, the patient experiences relief. The polypus does not admit of being pressed back, and, during an attempt to do this, the patient is put to much inconvenience. A probe may be introduced by the side of the polypus deeply to the fundus uteri. When passed by the side of the fallen uterus, it is very soon stopped at the upper part of the vagina, which has sunk down with the cervix of this organ.

It is much more easy to distinguish a polypus protruded externally from the vagina, from a perfect prolapsus uteri, without inversion. The os uteri at once characterises the uterus, as it can here not only be felt, but seen. A probe may be passed deeply into the vagina, along the side of the polypus; but, not so by the side of the uterus, for reasons easy of comprehension. Moreover, the figure of the tumour, and the state of the patient, on an effort being made to reduce the protruded part, betray its real nature.

The inversio uteri is commonly the consequence of a difficult labour, and hence is easily discriminated from a polypus, by its occasional cause. While the inverted uterus lies in the vagina, its shape is broad above, and narrow below; whereas the polypus is thin above, and broad below. Hence, in cases of very large polypi in the vagina, the os uteri is but little dilated; while it is extremely distended by the incomplete descent of the inverted uterus itself. Here, likewise, the reduction of the part is attended with relief; while every effort to push back a polypus causes an aggravation of all the complaints.

When the inverted uterus hangs out of the vagina, its figure, like that of the polypus, is thin upward, and broad downward; and, like the latter tumour, has no aperture at its lowest part. Here, an erroneous opinion is very liable to be formed. An attentive observer, however, will easily avoid it. The inverted uterus includes a circular fold at its upper part, next to the orifice of the vagina. This fold is nothing less than the os uteri itself, through which the body of this viscus has descended. There is nothing of this kind to be felt in cases of polypi. By the side of a polypus the finger or probe may be passed deeply into the vagina; but not so by the side of the uterus. The root of the polypus is firm and hard to the touch; the upper thin part of the uterus, which is hollow, has a soft flabby feel. Useful light is also generally thrown on the case, by the above-mentioned occasional cause of the prolapsus uteri with inversion.

In the two last descriptions of uterine polypi, which are situated either on the

inside of the cervix, or at the margin of the os uteri, the disease is, as it were, from its commencement in the vagina, and the tumour, when large, produces all the complaints attending polypi of the first kind, except frequent profuse bleedings. These seldom occur, and when they do, are slight, because the root of the polypus suffers no constriction in the os uteri. As it descends out of the vagina, it occasions a prolapsus uteri without inversion, in addition to the other inconveniences.

TREATMENT OF POLYPI OF THE UTERUS.

Experience proves, that uterine polypi, when once extirpated, have not that propensity to be re-produced, which those of the nose have. Extraction is not fit to be practised here for obvious reasons. Sometimes, however, uterine polypi are met with, which have such a thin and soft pedicle, that although they ought not to be pulled out, yet they admit of being twisted off with facility and safety. Also, numerous complaints of a serious nature, are occasionally the result of tying a polypus of the uterus. In this circumstance, after the ligature has been applied some days, we may attempt to shorten such complaints, by twisting off the tumour altogether. This object is most conveniently performed with a pair of forceps, made something like Smellie's midwifery forceps. As the part of the polypus in the ligature is constricted, thin, and already partly detached, the tumour, with a little caution, may frequently be easily twisted off, and that without any material bleeding. The actual and potential cautery are here unnecessary, as there is always room to employ the instruments for applying the ligature.

The ligature is the most proper means of extirpating uterine polypi, and is here much more easy of application, than in the nose. How large soever the polypus may be, there is always abundance of room for the introduction of the necessary instruments. The polypus of the uterus has, commonly, a thinner pedicle, than that of the nose; and, hence, its cure by the ligature is more expeditious, than that of the latter case. The swelling of the tumour, after the ligature is applied, occasions here far less inconvenience, than in the nose, on account of the greater room, and more yielding nature of the parts. The inconveniences that do arise, are easy of removal; for instance, the retention of urine may be relieved by the catheter: costiveness by glysters, &c. Uterine polypi are also less sensible, than nasal ones; and hence, less pain and fever follow the application of a ligature to them. The fetid matter, that forms as soon as the polypus sphacelates, has a free vent out,

and may easily be washed away by injections.

That the polypus cannot be tied, while it lies in the uterus, is easily comprehensible. But, immediately it has descended into the vagina, the operation may be undertaken, and may be performed with the same kind of double cannula, as was employed in the nose. However, here it is extremely requisite, that the cannula should be rather longer, than that already described, and somewhat curved. But, as the silver wire sometimes breaks, two other very convenient instruments have been invented.

The first is M. Levret's instrument. It consists of two silver cannulæ, which are curved in such a manner, and so united by a joint, that they are shaped like a pair of forceps. After introducing a ligature through the two tubes, so that its ends hang out of their lower apertures, the instrument is to be shut, and passed upwards into the vagina, over the polypus, on whichever side seems most convenient. Then it is to be opened, and the polypus is to be pushed through the two branches of the instrument, which is to be brought over the opposite side of the tumour. In doing this, the ligature becomes applied round the root of the polypus, and forms a noose. The extremities of the ligature are next to be drawn as tightly as possible out of the lower openings of the cannulæ, and tied first in a surgical knot, and then in a slip-knot. When this is done, the instrument is shut, and the ligature constricts the root of the polypus. Afterwards it is to be tightened daily, until the tumour separates.

It is plain, that this instrument has some defects, which are, however, easily amended. It is very inconvenient, that it should be necessary for the surgeon to have several such instruments, of various sizes, and curvatures, to be able to select that, which seems most calculated for the magnitude and shape of the polypus. Moreover, as the size and figure of the polypus cannot always be ascertained beforehand, it is often indispensable to try several instruments, ere the most suitable one is found out, and such fruitless attempts must be very irksome and painful to the patient. The worst is, that though the upper ends of the instrument were to touch, when the lower are tied together, yet there would always be a space between the two apertures, where no ligature would be applied to the root of the polypus, and where, consequently, its separation would not easily be accomplished. The tubes may, also, bend with the force used in applying them, and the pain caused by the expansion of the instrument, would then be very considerably increased.

All these defects are done away in the instrument described by Nissen, *de polypis*

uteri, (See *Richter's Chir. Bibl.* 9. B. S. 613.) It consists of two silver tubes, twelve inches in length, and as thick as an ordinary writing pen. Both are curved about as much as the os sacrum; but, as they are made of pure silver, the curvature may easily be increased or diminished, according to circumstances. Through each of the cannulæ a strong ligature is to be passed, so that its ends hang out of the lower apertures, while its middle portion forms a noose between the upper apertures of the cannulæ.

The tubes are to be kept together, until they have been introduced into the vagina, as far as the root of the polypus. One is then to be held fast, while the other is to be carried round the tumour, to the opposite side of the cannulæ that remains stationary. Thus the ligature becomes applied round the root of the polypus. After introducing the finger into the vagina, to ascertain that the ligature lies in its proper situation, its ends are to be drawn through a small double cannula, which is only one third of an inch long, but so wide that it can be pushed over both the tubes a certain way with the finger, and the upper end of the long cannulæ with the aid of a sort of long probe, with a forked extremity. Then a third double cannula, through which the ends of the ligatures have likewise been passed, and the width of which is sufficient, is to be pushed over the lower ends of the long cannulæ, so as to unite them. The ligatures are next to be drawn tight in the ordinary way, and fastened to the rings. The management of this instrument is so easy, as to need no further explanation.

This instrument is certainly far superior to any one commonly used in this country. It is difficult to pronounce, whether its simplicity; aptness for the object intended; or, the facility of using it; lays the greatest claim to our commendations. The same reasons, which recommend its employment in polypi of the uterus, equally point out the advantage of having an instrument, constructed on the same principle, for tying nasal ones.

Besides the above instruments, there are numerous other ones, that have been devised, and recommended for tying polypi of the uterus. That, invented by Desault, claims the attention of such surgeons as wish to be informed of others.

Acute symptoms frequently follow the application of the ligature, and are either of an inflammatory, or spasmodic kind. The former require antiphlogistic treatment. Sometimes a fever arises, and the polypus becomes exceedingly painful: in this case, venesection is often necessary. The spasmodic symptoms require the exhibition of opium. When this is ineffectual, and the symptoms are severe, it may

be proper to slacken the ligature a little. As the polypus at first always swells, it produces great pressure on the adjacent parts. For this reason, it is generally necessary, for the first few days, to draw off the urine with the catheter, and to open the bowels with glysters. Sometimes hemorrhage takes place. This is generally suppressed by astringents; but, when they prove ineffectual, tying the ligature more tightly answers the purpose. The rest of the treatment resembles that of nasal polypi.

When the polypus is large, forceps are, in the end, often necessary for its extraction. The inflammation, or ulceration, that may possibly be occasioned in the vagina by the fetid matter, is easily removed by injections after the detachment of the polypus. As the ligature is always applied round the pedicle, closely to the os uteri, consequently seldom to the root of the polypus, which is usually at the fundus uteri, there is almost always a portion of the root remaining behind, after the tumour has separated. Though it is said, that this afterwards diminishes, and falls off; yet, it is quite a matter of uncertainty. But, it is an undoubted fact, that the polypus uteri is seldom reproduced. (*Richter.*)

This author observes, that cutting instruments are, in general, improper to be used for polypi of the uterus, as their employment would injure the vagina, and for the most part, occasion a dangerous hemorrhage. There is, however, one case, where the knife is indispensable. The polypus has occasionally a ligamentous pedicle, and consequently can neither be tied, nor extracted. This circumstance is usually undiscovered till after a ligature has been applied, which here commonly produces extraordinary pain, and, though it be applied ever so long, and forcibly, occasions no detachment of the polypus. In this instance, the surgeon has the choice of two plans. He may either cut off the polypus closely to its root in the vagina; or he may first draw it gradually downward out of this situation. The first object might, perhaps, be performed with a sharp hook, somewhat curved at its side, and similar to what is used for tearing the fœtus piecemeal in the uterus; or, with what seems better, a pair of long curved, blunt-pointed scissors. The last object may be accomplished with forceps resembling Smellie's midwifery ones. They are to be introduced into the vagina in the ordinary way. The polypus is then to be taken hold of, and gradually drawn so far out of the vagina, that its pedicle may be divided with a knife. This is, indeed, not done without pain, and a forcible inversion of the uterus; but, it is always free from dangerous consequences. When a polypus, the root of which is attached to the fundus uteri, lies

in the vagina, the uterus is always, in some degree, inverted beforehand; and this state is, therefore, only increased by the foregoing plan, which never creates danger, when done slowly, and cautiously. How often has the uterus been suddenly inverted, and forced outward, without fatal consequences! Besides, the above plan has already been successfully practised. (*See Herbiniaux, Parallèle des différens Instrumens pour la Ligature des Polypes.*)

When a polypus, that has its pedicle attached to the fundus uteri, suddenly falls downward, it occasions a sudden inversion of this viscus. In order to relieve, as speedily as possible, the great pain, and danger of this case, the surgeon must tie the root of the polypus, as soon, and as firmly as he can, and pass the ligature, by means of a needle, through the pedicle, before the place where it is tied, allowing the ends afterwards to hang down for some length. Then the polypus is to be amputated below the ligature, and the uterus immediately reduced. This is another example, where a cutting instrument may be used with advantage. The ordinary method of tying such tumours, so situated, accomplishes only a slow detachment of them, and is not sufficiently expeditious in procuring relief.

Fleshy excrescences also occasionally form in the vagina, some of which have a broad basis, and others a thin pedicle. The last merit the appellation of polypi. Their existence is easily ascertained by the touch. By making pressure on the bladder, and rectum, they occasion several impediments to the evacuation of the urine, and feces. They may be most conveniently tied, by means of the double cannula. Should the polypus be situated at the lower part of the vagina, the cannulæ would not be required. The ligature might be applied with the hand, and the tumour cut off below the constricted part.

There is still another kind of tumour in the vagina, to be classed in the rank of polypi. It resembles, in many points, the polypus of the mucous membrane of the nostril, consisting altogether of the membranous lining of the vagina, which, at the part affected, becomes relaxed, thickened, and elongated; hence, the tumour might more properly be termed a *prolapsus of the membrane lining the vagina*, than a polypus. When it resists the efficacy of astringent and corroborant injections, it may be tied, or, what is better, cut off.

A polypus in the œsophagus renders deglutition difficult; and, when of large size, puts an entire stop to it. When an inclination to vomit is excited by irritating the throat with the finger, or a feather, the polypus, if situated towards the upper part of the tube, ascends into the mouth, so as to become visible. But, as it impedes respiration during its residence in the mouth,

the patient is soon necessitated, as it were, to swallow it again. When the polypus is situated at the lower part of the œsophagus, of course, it cannot be brought into the mouth, and is very difficult to detect. The difficulty of swallowing, its only symptom, may result from other causes. In this case, it is also incurable; for, it is impossible to take hold of it with instruments. An operation can only be practised, when the polypus is situated at the upper part of the œsophagus. The tumour obviously cannot be extracted; it can only be tied, and this is difficult. In order to apply the ligature, the excrescence must be first brought into the mouth by exciting an effort to vomit. As this impedes respiration, the operation must be done with the utmost celerity, and the ends of the ligature cut off short, that the patient may immediately swallow the tumour again. It is easy to discern, that in this way, the ligature is never applied sufficiently close to the root of the polypus, nor tightly enough; consequently, the separation of the tied portion either does not take place at all, or very slowly; and a large part commonly remains behind, which soon attains its former bulk, and causes its preceding inconveniences. Perhaps, the operation might be performed with more exactness, and success, if an opening were previously made into the trachea by bronchotomy. Then the patient might breathe through the aperture; the polypus might continue in the mouth during the whole cure, until detached; and, perhaps, might be tied close to its root, by means of a curved tube. Experience (adds Richter) must decide, whether this plan is advantageous, and practicable.

Polypi in the rectum may be felt by the fingers. The first suspicion of them arises from the impediment to the evacuation of the excrement. They are to be tied with the aid of the cannulæ. Excrescences in the meatus auditorius externus, resembling polypi, have been successfully extirpated by extraction; or rather by twisting them off.

For many of the foregoing remarks, I am indebted to Richter, who has very ably treated of polypi in his *Anfangsg. der Wundarzn. Band. 1, Kap. 21.* See also Pott's *Remarks on the Polypus of the Nose.* Whateley's *Two cases of extraordinary Polypi.* John Bell's *Principles of Surgery, Vol. 3, Part 1.* *Encyclopédie Méthodique; Art. Polype.* Lassus, *Pathologie Chirurgicale, Tom. 1, p. 528—538, &c. Edit. 1809.* Callisen's *Systema Chirurgiæ Hodiernæ, Vol. 2, p. 169, &c.*

PORRIGO. See *Tinea Capitis.*

PROCIDE'NTIA. A prolapsus, or falling down of any part. (See *Anus, Prolapsus of; Uterus, Prolapsus of, &c.*)

PROLA'PSUS. A falling down of any part. Same as *Procidentia.*

PROSTATE GLAND, DISEASE OF.

According to Sir E. Home, the prostate gland is not a very sensible part. Dr. Baillie has seen a common abscess situated in it, and he says, that it is also subject to scrophulous disease, as, on cutting into it, he has met with the same white curdy matter, which is formed in a scrophulous absorbent gland. He has likewise forced out of its ducts scrophulous pus.

The most frequent disease of this part is a scirrhus enlargement of it, when, from its natural size of a chesnut, it becomes as large as the fist. When cut into, it exhibits a very firm whitish, or brown substance, containing membranous septa. Sometimes its external surface is ulcerated, though this is not often the case; and fistulous communications are occasionally formed with the rectum. A considerable enlargement of the prostate gland is attended with great difficulty of voiding the urine, and the muscular coat of the bladder becomes, in consequence of the efforts it has to make, very much thickened. This disease of the prostate gland seldom occurs, except in old men, and is not so common as many suppose. Sir E. Home observes, that the morbid enlargement of the gland does not diminish the size of the passage into the bladder, but rather increases it. The lateral portions of the gland as they swell, widen the passage between them, rendering it of an oval form; it is therefore the projecting portion, from the lower part, which prevents the urine from flowing, and obstructs an instrument in its passage into the bladder. The obstruction, in some instances, arises from the two sides of the gland enlarging unequally; the larger portion pressing upon the smaller, which is made hollow to receive it, so that the passage winds round the projecting part, and this winding cannot be followed by an instrument.

Sir E. Home remarks, that a stricture may be distinguished from an enlargement of the prostate gland, by the following circumstances: the distance of the obstruction from the external orifice is to be determined by passing a soft bougie, which is to be left in the canal for a minute, so as to receive an impression from the obstruction. If the bougie does not pass further than seven inches, and the end is marked by an orifice of a circular form, (it is immaterial as to the size of the orifice,) the disease is certainly a stricture; but, if it passes further on, and the end is blunted, a disease in the prostate gland is to be suspected. This in general can be ascertained by a flexible gum catheter with a stilet, very much curved, passing into the bladder, which it will do, in most cases of enlargement of the gland.

Among the symptoms of a diseased prostate, we have also to mention, a difficulty of voiding the feces; an occasional dis-

charge of a kind of mucus; an uneasy sensation about the rectum, after going to stool, as if more of the feces remained undischarged. The difference between the symptoms of a stone in the bladder, and those arising from disease of the prostate, is explained in the article *Lithotomy*.

The occasional retentions of urine, to which patients with disease of the prostate are subject, require the introduction of the catheter, and the surgeon will succeed in passing this instrument better, when he remembers, that the urethra, in consequence of the disease, makes a very sudden turn upward, just before it terminates in the bladder.

The enlargement of the prostate gland may often be felt by passing a finger into the rectum. Surgeons are unacquainted with any certain mode of diminishing the scirrhus enlargement of the prostate gland. The *pilula hydrargyri cum cicutâ* have been recommended. (See *Pilulae*.) Sir E. Home mentions a case, in which suppositories of opium and hemlock, passed up the fundament, and allowed to dissolve there, gave more relief, than any other plan; they not only lessened the irritation, but produced a diminution of the projection of the gland.

Some abscesses, and ulcerations of the prostate, in consequence of strictures, may be cured, by removing the latter disease.

The prostate gland has occasionally small calculi in its ducts: but, the disease is so uncommon, that authors have not ascertained the particular symptoms, &c. I shall conclude with referring to *Baillie's Morbid Anatomy*; *Home on Strictures*, Vol. 1, and on *Diseases of the Prostate Gland*.

PSEUDOSYPHILIS. (from *ψευδης*, false, and *Syphilis*, the venereal disease.) Disease, resembling the venereal, but not really of this nature. The spurious venereal disease. (See *Venereal Disease*.)

PSOAS ABSCESS. See *Lumbar Abscess*.

PSOROPHTHALMY. (from *ψωρα*, the itch, and *οφθαλμια*, an inflammation of the eye.) An inflammation of the eyelids, attended with ulcerations, which itch very much. By psorophthalmy Mr. Ware means a case, in which the inflammation of the eyelids is attended with an ulceration of their edges, upon which a glutinous matter lodges, incrusts, and becomes hard, so that, in sleep, when they have been long in contact, they become so adherent, that they cannot be separated without pain.

Mr. Ware remarks, that "the ulceration in the psorophthalmy is usually confined to the edges of the eyelids; but, sometimes, it is seen to extend over their whole external surface, and even to excoriate the greater part of the cheek. In cases of the latter kind, the inflammation which accompanies, has often much the

appearance of an erisypelas, and will receive most relief from cooling applications. The use of the citrine ointment, which will hereafter be recommended, must, in such instances, be deferred until the irritability of the skin is in a good degree abated.

"This disorder is also, sometimes, attended with a contraction of the skin of the lower eyelid; in consequence of which, that lid is drawn down, and the inner part turned outward, so as to form a red, fleshy, and most disagreeable appearance, called ectropium. Whenever this happens, it proves the complaint to be of the most obstinate nature; though it is generally removed by the cure of the psorophthalmy, which is the occasion of it." (*Remarks on Ophthalmy*, &c. p. 112.) Mr. Ware recommends, for the cure of this disease, the unguentum hydrargyri nitrati. This is to be melted into an oil, and rubbed with the end of the forefinger, or the point of a small pencil-brush, into the edges of the affected eyelids, once every night, on going to bed. A plaster of ceratum album is then put over the eyelids to keep them from adhering together. If they should still adhere in the morning, he advises cleaning them with milk and butter, well mixed together. In a few cases, it is necessary to touch the ulcers, formed on the edge of the eyelid, after the small-pox, with the argentum nitratum. When the globe of the eye is inflamed, use the thebaic tincture, as directed in the article *Ophthalmy*. In scrophulous subjects, alterative medicines; an issue, or perpetual blister; and attention to diet, &c. are proper. (See *Ware on Ophthalmy*, &c.)

PTERYGIUM. (dim. of *πτρυξ*, a wing.) Scarpa accurately remarks, that surgeons apply the term "*pterygium*" to that preternatural, reddish, ash-coloured, triangular little membrane, which most frequently grows from the internal angle of the eye, near the caruncula lachrymalis, and gradually extends over the cornea, so as to cause considerable impediment to vision.

Though the pterygium most commonly proceeds from the internal angle, it is observed to arise sometimes from the external one, and, in some instances, from the superiour, or inferiour hemisphere of the eye-ball. But, whatever be its origin, its figure is invariably that of a triangle, with its base on the white of the eye, and its apex more or less advanced over the cornea, towards its centre, and that of the pupil. Indeed, there are a few cases, in which two, or three pterygia of different sizes occur on the same eye, and are arranged round its circumference at interspaces of various breadths. Their points are directed towards the centre of the cor-

nea, and if they should unfortunately conjoin there, the whole of that transparent membrane becomes covered with an opaque veil, and a total loss of sight is the consequence. It seems to Scarpa, that the term "*pannus*" was applied by the ancients to exactly this sort of complication.

Strictly speaking, chronic varicous ophthalmia, with relaxation, and thickening of the conjunctiva; opacity of the cornea; and the pterygium; only differ in the degree of the disease. In reality, all the three complaints consist of a more, or less extensive varicous state of the vessels of the conjunctiva, combined with a degree of preternatural relaxation, and thickening, of that membrane.

In chronic varicous ophthalmia, the extraordinary amplitude, and knottiness of the vessels; the flaccidity, and thickening of the conjunctiva; are limited to the white of the eye. In opacity of the cornea, certain veins even dilate, and become knotty, for some way, over that delicate layer of the conjunctiva, which is continued over the surface of the cornea. In the pterygium, an extraordinary swelling of this subtile membranous expansion is added to the varicous state of its veins. Hence, the pterygium seems at first like a new membrane formed on the cornea, while it is really nothing more, than the delicate continuation of the conjunctiva just mentioned, deprived of its transparency, and degenerated, in consequence of chronic ophthalmia, into a thick, opaque membrane, on which there is a plexus of varicous blood-vessels. Consequently, in the case of pterygium, there is no new production on the eye, but only an alteration of one of the thin, transparent membranes, which naturally cover it. The following circumstance, as will be more fully explained presently, illustrates, says Scarpa, the veracity of the preceding statement. The incipient pterygium may be cured in the same manner as opacity of the cornea, viz. by merely cutting off that portion of it, which is situated at the junction of the cornea with the sclerotica, without detaching the whole of it from the surface of the former membrane; just as is practised in opacity of the cornea, in order to destroy the communication of the varicous veins of the conjunctiva with their trunks, the ramifications of which produce, and maintain the disease.

Scarpa observes, that the pterygium would be as common a complaint as the varicous chronic ophthalmia, so often occupying the white of the eye, if the delicate continuation of the conjunctiva, over the surface of the cornea, were not naturally of a denser, and more compact texture, than the rest of the membrane, from which it is produced, and if its vessels

were not very minute, and delicate, and not so dilatable as those of the other part of the conjunctiva. This is the reason why the pterygium is comparatively a rare case, in respect to the great frequency of varicous, chronic ophthalmies. But, should the vessels of the transparent layer of the conjunctiva once yield to the impulse of the fluid propelled into them; should they once become varicous; the cellular texture, in which they are enveloped, never fails to swell gradually, and, thus, the delicate, diaphanous membrane in question, changes into a pulpy, reddish tunic, precisely similar to the pterygium.

That the pterygium is truly nothing else but the natural, delicate, transparent expansion of the conjunctiva, on the cornea, converted, for a certain extent, into a pulpy, flaccid varicous membrane, may be inferred (continues Scarpa) from the folds, which the pterygium and conjunctiva form at the same time, when the morbid eye is turned towards the origin of the disease. The same inference is equally deducible from the tension occasioned in both these parts, whenever the eye is moved in the opposite direction. We become still more convinced of the fact on observing, that in the first position of the eye, both the pterygium and the corresponding portion of the conjunctiva (which is equally relaxed, varicous, and reddish), may be easily taken hold of with a small pair of forceps, and raised together in the form of a fold.

When the pterygium is met with in the dead subject, on carefully cutting off, and detaching, that flaccid, and thickened portion of the conjunctiva, in the white of the eye, which corresponded to the part of the cornea in the state of opacity from the pterygium, Scarpa has constantly found, that the pterygium might be separated, with equal facility, both on the white of the eye, and the cornea. The latter membrane was evidently denuded at the seat of the disease, being no longer covered with the transparent continuation of the conjunctiva. But, Scarpa has never been able to deprive the cornea of its natural covering, beyond the limits of the pterygium. Also, when several pterygia occur on the same eye, with interspaces between them, as many flaccid, varicous, pulpy places appear in the conjunctiva on the bulb, and constitute the basis of the pterygia; while the rest of this membrane, covering the white of the eye, continues smoothly spread over the ball, and no varicous blood-vessel is perceptible on the anterior hemisphere of the eye, except where the relaxation of the conjunctiva, and the knottiness of the vessels, have implanted, as it were, the distant roots, and rudiments of the pterygium.

The pterygium, whether large, or small,

and whatever its situation may be at the circumference of the eye-ball, constantly retains its triangular shape, with its base on the white of the eye, and its apex on the cornea. The constancy of this fact seems to Scarpa attributable to the increasing degree of firmness, with which the subtile, transparent layer of the conjunctiva adheres to the surface of the cornea, as it proceeds from the circumference to the centre of that membrane. The following consequences must necessarily result from this sort of structure, and the different degree of cohesion, actually existing in healthy eyes. 1. The progress of the pterygium must be slower in every instance on the cornea, than on the white of the eye. 2. As the pterygium always meets with augmented resistance, in proportion as it endeavours to approach the centre of the cornea, it must from mechanical necessity assume the form of a triangle, with its base on the white of the eye, and its apex directed towards the centre of the cornea. Forestus (*Oper. Med.*) has accurately noticed the circumstances of this appearance, and, he continues: *non cooperit oculum nisi in formâ sagittæ.*

From this invariable appearance, and figure of the pterygium, one of its principal diagnostic characters results, by which the true disease may be discriminated from false instances, and from every other soft, fungous, reddish excrescence, that obscures the cornea. For, on this membrane, excrescences sometimes form, which, from having the colour and consistence of a soft membrane, bear a very great resemblance to the pterygium, though they are really widely different, and, strictly speaking, consist of the texture of the cornea itself, degenerated into a soft, fungous substance. Such pellicles, however, not only almost always create a greater prominence on the cornea, than what accompanies the pterygium, but they are constantly of an irregular tuberculous form, and never represent a triangle, with the apex pointing towards the centre of the cornea, like the genuine pterygium.

Another distinguishing character of the pterygium (continues Scarpa) consists in the facility, with which the whole of it may be taken hold of with a pair of forceps, and raised into a fold on the cornea. Every other kind of excrescence, attached to this membrane, continues firmly adherent to it, and cannot be folded, and raised from the surface of the cornea, in any manner whatever. This particularity is of the highest importance in the treatment of the disease; for, the genuine pterygium may be cured by simple means, while fungous excrescences of the cornea, can only be radically removed, and

perfectly cicatrized with the utmost difficulty. Plenck very properly observes, on this head: *Pterygia, quæ filamentis solummodò adherent, faciliè abscinduntur, difficilimè quæ ubique accreta sunt corneæ, ac in plicam elevari non possunt.* If this excrescence should adhere firmly to the cornea, be of a deep red colour, easily bleed on being touched, and cause shooting pains in the whole eye, and temple, though it be of a triangular figure, and constitute the true pterygium, it now threatens to assume a malignant cancerous nature, or has done so already. Hence, in the treatment, it is necessary only to adopt a palliative plan, or else extirpate the whole eye-ball.

The true, benign pterygium, says Scarpa, which has a triangular figure, is ash-coloured, or pale-red, is free from pain, and admits of being raised in the form of a fold on the surface of the cornea, may be cured by cutting the opaque triangular little membrane accurately from the surface of the cornea, which is in part covered by it. But, as it appears, from what has been said, that the pterygium is nothing, but a portion of the delicate, transparent layer of the conjunctiva converted by chronic varicous ophthalmia into a thick, opaque tunic, it follows, that the pterygium cannot be removed in any way, without the spot, which it occupies on the cornea, being bereft of its natural external covering. Also, as this denudation of the cornea renders a cicatrix unavoidable at the place, it equally follows, that the knife cannot be employed in the cure of the disease, without the cornea being rendered more or less opaque at the part, where the pterygium was before situated. Hence, Scarpa cautions young surgeons not to allow themselves to be deceived by the specious accounts of authors, who assert, that they have removed pterygia with the scalpel, and entirely restored to the cornea its former natural transparency. It is true (says he) that, after the removal, and cure, of the pterygium, the cornea at the part affected becomes less opaque, than it was before; but, the place always continues dim, and clouded with an indelible, though a superficial cicatrix. The amendment, derived from the operation, cannot but be considerable; by means of the incision, and firm cicatrix, a stop is put to the progress of the complaint, or rather to the increase of the varicous affection, and swelling, of the thin, transparent layer, of the conjunctiva, situated on the cornea; the local cause of irritation, and inflammation of the eye, is entirely obviated; and, thus, complete opacity of the cornea is prevented. But should it ever have happened after the recision of a large pterygium, that the

patient regained his sight, we are to understand a certain degree of vision; in that proportion (Scarpa wishes to signify) which exists between a dense membrane, which entirely obstructs the passage of the light, and a slight, superficial cicatrix of the cornea, which does not intercept it altogether.

Scarpa's experience enables him to state, however, that the superficial, indelible speck, remaining on the cornea, after the recision of the pterygium, is always less extensive, than the space previously occupied by the disease. This fact, says he, is a constant one, and, in the vast number of pterygia, for which he has operated, some had advanced over the cornea two lines, others two and a half, towards its centre. In all, the scar, and opacity, of the cornea, diminished after the cure was perfected, and never exceeded a line and a half, or a little more, in cases, in which the pterygia had been two lines in length.

The recision of the pterygium is a very easy operation. For this purpose, there is no occasion for a needle threaded with silk, which most surgeons recommend to be passed through the little membrane, in order to make a noose for raising the pellicle, which must be divided at its base. The plan is disadvantageous, as it prolongs the operation considerably, and, particularly, as the bleeding from the punctures prevents the operator from distinguishing, with the necessary clearness, the margin of the parts designed for removal. A pair of dissecting forceps, and a pair of sharp scissors, suffice for this operation.

It is customary (continues Scarpa) to remove the pterygium by making the incision on the cornea, and extending it over the white of the eye, as far as the base of the disease reaches on the conjunctiva; so that when the pterygium grows from the internal angle of the eye, most surgeons continue the section as far as the caruncle. This practice is disadvantageous, first, because it denudes too much of the white of the eye; secondly, because, in consequence of the large portion of the conjunctiva removed at the base of the pterygium, and, in consequence of the direction of the wound, the cicatrix in the white of the eye, forms an elevated frænum, which, like a little cord, keeps the eye-ball approximated to the caruncula lachrymalis, and destroys the freedom of its motions, particularly, towards the external angle.

To avoid this inconvenience, Scarpa says, he has found it useful, in the treatment of pterygia with bases extending far in the white of the eye, to detach them at their apex, as far as the junction of the cornea with the sclerotica, and then

to separate them at their base by a semicircular incision, comprehending one line in breadth of the substance of the conjunctiva, and made in a direction concentric with the edge of the cornea. Scarpa has observed, that, in this mode of operating, the subsequent cure takes place sooner, than when the common method is adopted; the cicatrix occasions no sort of frænum, and the conjunctiva, circularly stretched by the cicatrix, lies smoothly over the white of the eye, and loses that relaxation, and varicous state, which are the groundwork of the pterygium. Such attention, however, is not requisite, when the pterygium is small, and its base does not extend far in the white of the eye.

Scarpa describes the operation, as follows: The patient being seated, an assistant behind him is to elevate the upper eyelid with the index and middle fingers of one hand, while he depresses the lower eyelid with the corresponding ones of the other. Supposing it the right eye, the operator is to stand, or sit down, just as he prefers, in front of the patient; and the former, after directing the latter to move his eye-ball towards the part corresponding to the base of the pterygium, is to seize the morbid membrane with a pair of forceps held in his left hand, and pinch it into a fold, at about one line from its apex. The duplicature is now to be raised, and drawn out gently until a sensation of something giving way is felt, which indicates the detachment of the pterygium from the delicate cellular texture, by which it is connected with the subjacent cornea. Next, by means of a pair of scissors in the right hand, the surgeon must dissect this fold, as closely as possible, from the cornea, proceeding from the apex towards the base of the pterygium. The section being completed to where the cornea and sclerotica meet, the fold is to be again elevated still more, and, with one stroke of the scissors, the pterygium, and the relaxed portion of the conjunctiva, forming its base, are to be detached, as concentrically, and closely to the cornea, as possible. This second incision will have a semilunar shape, the horns of which ought to extend two lines beyond the relaxed part of the conjunctiva in following the curvature of the eye-ball.

When the operation is finished, the surgeon must promote the hemorrhage, by washing the part with warm water, and then cover the eye, that has been operated on, with a pledget of dry lint, or lint moistened in the aqua vegeto-mineralis, supported by a bandage, that does not make too much pressure on the part.

If no particular symptoms arise, (continues Scarpa) such as pain, tension of the eye, considerable tumefaction of the

eyelids, it is sufficient to wash the eye, and inside of the eyelids, three or four times a day with a warm lotion of mallows, and carefully keep these parts from being exposed to the air, without compressing them. If the symptoms just mentioned should afterwards occur, the antiphlogistic treatment must be adopted in its full extent, &c.

On the fifth or sixth day, at latest, after the operation, all the surface, from which the pterygium was cut, appears yellowish, and covered with a fluid, like mucus. This is a mode of suppuration (says Scarpa) peculiar to membranes in general, and particularly, to those of the eye. The edges of the wound, and the adjoining part of the conjunctiva, assume a reddish colour. Afterwards, the surface of the wound contracts more and more daily, so that, at length, it completely closes, and the cicatrix forms.

During the whole treatment, subsequent to the operation, there is no occasion to employ any other topical applications, but the warm lotion of mallows, three or four times a day. Numerous cases have convinced Scarpa, that astringent collyria, and the boasted powders of the florentine iris, and alum, cause great irritation to the eye operated on, and give rise to tumefaction, and a fungous-like state of the conjunctiva, which are impediments to the cure. What is still more incommodious, is, that such means produce fungous excrescences on the middle of the wound itself, which only admit of being repressed and cicatrized with difficulty. Scarpa has seen all these inconveniences arise from one single unnecessary application of the *argentum nitratum*. On the other hand, when a mere lotion of mallows is the only remedy employed in the treatment, the cure proceeds regularly; the yellowish surface of the incision diminishes daily, and in three, or, at most, four weeks, the wound is quietly healed. The vitriolic collyrium, containing a few drops of camphorated spirit of wine, can only be prudently instilled, three or four times a day, into the eye, for the purpose of strengthening the conjunctiva and its vessels, after the wound is perfectly cicatrized.

We have already repeated Scarpa's sentiment, that the incipient pterygium, strictly speaking, is nothing more than an opacity of the cornea, in which the venous vessels of the conjunctiva covering that part of the cornea, which is the seat of the disease, are somewhat more dilated, than in the case, to which the term, "*opacity*," is usually assigned; and also, that the density, and opacity, of the delicate layer of the conjunctiva are much more considerable, at the part affected, in the instance of pterygium, than in that of simple opacity of the cornea.

The incipient pterygium (adds this author) is not a dense, opaque membrane, but a pellicle as fine as a cobweb, interwoven in different places with varicous blood-vessels, the iris continuing tolerably visible behind it. In this early state of the pterygium, it is unnecessary to deprive the cornea of its natural covering; it is quite enough to cut off a portion of it, in order to intercept all communication between the dilated venous ramifications of the pterygium, and the varicous trunks in the white of the eye.

The recision, says Scarpa, is accomplished by cutting out, with a pair of forceps and scissors, a semilunar piece of the conjunctiva, at the point where the cornea and sclerotica conjoin, and exactly at the base of the incipient pterygium, just as is practised for opacity of the cornea. The recent pterygium is observed to disappear gradually after the operation, or to change into a slight dimness of the cornea, extending over a part of the space previously occupied by the disease. This opacity is commonly much more trivial, than what follows a cicatrix. Acrel, in his *Surgical Observations*, mentions having successfully treated an incipient pterygium in this manner. Scarpa has also tried the plan several times with success. Scarpa *sulle Malattie degli Occhi*, cap. 11. See also Callisen's *Systema Chirurgiæ Hodiernæ*, Vol. 2, p. 163, &c. Edit. Hafniæ, 1800. PTOSIS. (from *πτωω*, to fall down.) An inability of raising the upper eyelid. The affection may be owing to several causes, the chief of which are a redundancy of skin on the eyelid; a paralytic state of the levator muscle, a spasm of the orbicularis. Ptoxis from the first cause may be cured by cutting away the superfluous quantity of skin. When the case depends on paralysis, the surgeon may try bathing the eye and surrounding parts with cold spring water, and rubbing the eyelid and eyebrow with any liniment containing a little of the tincture of cantharides. The linimentum camphoræ; the shower bath; and bark; may also be occasionally tried. The spasmodic ptoxis requires antispasmodic medicines; the application of a blister to the temple; and fomenting and bathing the eye and eyelids with a decoction of cicuta, or poppy-heads.

PUNCTURED WOUNDS. See *Wounds*.

PUPIL, CLOSURE OF. An inconvenience, not frequent indeed, but which however sometimes follows the opera-

tions of depression, and extraction, is a closure of the pupil in such a degree, that it becomes almost or quite shut, attended at first with a diminution, and afterwards with an entire loss, of sight.

This unpleasant occurrence, says Scarpa, is most frequently the consequence of a vehement inflammation of the internal membranes of the eye, especially, the iris, occasioned by the extraction, or depression, of the cataract. In some particular instances, this inconvenience follows one of these operations, but without the inflammation of the internal parts of the eye, and especially of the iris having any share in its origin, at least, as far as we can judge from appearances. In such circumstances, after an indeterminate time from the operation of depression, or extraction, the pupil is perceived to diminish in diameter daily, without any evident cause, so that at last it becomes, as it were, entirely obliterated, and that without the patient complaining of any uneasiness in the eye, if we except in a few individuals, a greater sensibility, than is natural, in the immediate organ of vision, even to a very moderate degree of light. In both cases, the pupil ordinarily closes so much, that it can hardly admit a small pin's head, and continues motionless; while within the situation of the pupil itself, the iris assumes a stellate, rugose appearance, with a little irregular aperture in the centre, behind which, when the cataract has been extracted, or depressed, the deeper part of the eye seems black; or, if a portion of the anterior convexity of the opaque crystalline capsule should chance to remain behind after one of these operations, and has subsequently come into contact with, and adhered to, the posterior surface of the iris, a small whitish speck, or veil, may be seen there.

Theory has induced some to suppose, that, when this morbid closure of the pupil originates from an excessive distention of the vessels of the iris, in consequence of severe inflammation affecting that membrane, it may be cured by means of local and general bleeding, purgatives, blisters, and a seton in the nape of the neck. On the other hand, they have deemed emollients, and internal and external antispasmodics, serviceable, in the instance of constriction of the pupil arising from spasm of the iris, and increased morbid sensibility of the immediate organ of sight, in consequence of the sympathy of the latter with the iris. But, how plausible soever these curative indications may seem to be for the closure of the pupil, practice has not admitted their efficacy. On the contrary, says Scarpa, it has clearly evinced, that this disease cannot be remedied, except by making an artificial opening in the iris, as a substitute for the natural pupil, now wholly,

or partly obliterated, and as an aperture, which is to do the functions of the original one.

The young surgeon will probably have great difficulty in forming a judgment of the merits of the numerous methods of forming an artificial pupil, because, each plan is recommended by some great name, and supported by unquestionable examples of success; nor do I know at present how so many discordant opinions can be reconciled. Every writer describes his own method as the best. The truth is, each mode will succeed, when skilfully executed, and perhaps more depends on the manner of operating, than the kind of operation. Cheselden's plan is highly recommended by its ease and simplicity; while the modern observations of Ware, Adams, and Roux prove that the reason for which it was too hastily abandoned, viz. the closure of the opening again, is not well founded. Gibson's method is also simple and easy. I much doubt, whether the operations of Scarpa and Maunoir are better.

Before proceeding further into the subject, however, I think it will simplify it very much to state, that numerous as the plans of operating are, they may all be classed under three principal methods. 1. The simple transverse, or perpendicular incision of the iris. 2. The excision of a piece of this membrane. 3. The separation of a part of it from its circumference, or the ciliary ligament. (See *Roux, Parallèle de la Chirurgie Angloise*, &c. p. 286.)

To the best of Scarpa's knowledge, Cheselden was the first, who ventured to devise, and execute, a section of the iris, for the purpose of forming an artificial pupil. He introduced a couching needle, having a sharp edge only on one side, through the sclerotica, at the distance of a line and a half from the cornea, into the interior of the eye. After perforating the iris towards the external angle, and then pushing the point of the needle through the anterior chamber of the aqueous humour, as far as that side of the iris, which is nearest the nose, he turned the edge of the instrument backward, and withdrew it, so as to make a transverse division of the iris.

It is related, that this operation was attended with the greatest success. However, Janin (*Mem. sur l'Œil*) assures us, that, having performed it on two subjects with the utmost care possible, he did not find the smallest benefit follow it; for, in these two patients, as soon as the symptoms, produced by the operation, subsided, he found the transverse section, made in the iris by the edge of the needle, re-united, and consolidated. Sharp had experienced the same thing, before Janin. (*On Operations*, chap. 29.)

An accident occurred to Janin, in the act of extracting a cataract; viz. he included the iris together with the cornea, in Daviel's scissars, and cut it perpendicularly. This circumstance taught him, as he expresses himself, that a perpendicular section, made in this membrane, on one side of the pupil, was the only truly efficacious method of preventing the edges of the wound of the iris from growing together again, so as to form a durable artificial pupil. This is exactly what led this oculist to make it an operative method, and to propose it, as the best expedient for making an artificial pupil. His plan consisted in opening the cornea, as is practised for the extraction of the cataract, and in dividing the iris perpendicularly with scissars, near that part of the pupil, which is next to the nose, and he affirms, that he has seen strabismus result from making the section towards the external side, on account of the too great divarication of the optical axes.

In the small number of cases of closure of the pupil, which Scarpa has seen and treated, as consequences of the operation of the cataract by extraction, or depression, he has never been able to make up his mind to open the cornea, in order to accomplish with scissars the perpendicular section of the iris, as proposed by Janin, or with the knife, as recommended by any other person. He has felt conscious of the frequent severe symptoms, which arise from making an opening into the cornea, when the eyes have already been affected, after the first operation, with violent internal ophthalmia, spasm, and morbid increase of sensibility in the immediate organ of sight. He says, he will never cut the cornea again after the extraction of the cataract, lest an irregular cicatrix should be the consequence. He is the less inclined to do so, as he is convinced, that it is not so easy, as some may conceive, to divide the iris, with scissars, when it has become flaccid in consequence of the escape of the aqueous humour. Scarpa had had occasion to see more frequently, than once, the edge of the iris detached, by blows on the eye-ball, from the ciliary ligament, to the extent of two lines, and without any laceration of the body of this membrane. At the place where the iris had been separated from the ciliary ligament, he says, he had seen an oval fissure remain during the rest of the patient's life, and it might have answered every purpose of an artificial pupil, had not the immediate organ of vision, and the crystalline, in the instances alluded to, suffered too severely from the violence of the blow. In a case of prolapsus of the iris, through a small ulcer of the cornea, where the former part was very much dragged, in consequence of the large portion of it protruded, and the

adhesion, which it had contracted with the edges of the ulcer of the cornea, Scarpa had remembered, that this same part, the iris, instead of being lacerated at its middle, had rather been detached, for a certain extent of its circumference, from the ciliary ligament, so as to produce there an artificial pupil, which was very serviceable to the patient after the cure of the prolapsus of the iris. Scarpa likewise called to mind, that in depressing a cataract, he had seen a similar separation of the margin of the iris from the ciliary ligament take place, in consequence of having merely pushed the opaque crystalline inadvertently against the internal edge of this membrane, at the moment, when the lens continually rolled round the spear of the straight needle, without his being able to seize it, so as to immerse and depress it deeply in the vitreous humour. Besides these circumstances, it had often occurred to him to observe in frequent dissections of the eye, that on taking hold of the iris with forceps, and pulling it, not only at a little distance from its greatest disk, but also at the very edge of the pupil, this delicate membrane more readily became detached from its junction with the ciliary ligament, than lacerated at its middle, although it is certainly of a very soft nature. Lastly, it cannot be doubted, that the iris is a membrane perfectly distinct from the choroides, and has a proper, though feeble, connexion with the ciliary ligament, independently of the union of the choroides with the same ligament.

All these considerations taken together, especially that of the feeble union of the iris with the ciliary ligament, and, consequently, of the greater facility of detaching the edge of the iris from the ligament, with which it is connected, than of lacerating the body of this membrane, have induced Scarpa to try a new method of forming an artificial pupil, when the natural one has become too much contracted, or quite obliterated, after the extraction, or depression of the cataract. This method of operating, consists in detaching, by means of a couching needle, a certain extent of the circumference of the iris from the ciliary ligament, without ever preceding this operation by a section of the cornea. The attempt met with success.

The patient being seated, and supported, as if he were about to have the operation for the cataract performed, a straight couching needle, not so large as that which most surgeons use, but slender, like that which Scarpa prefers, (see *Cataract*,) is then to be introduced through the sclerotica, at the external angle of the eye, about two lines from the union of this membrane with the cornea; and its point is to be pushed as far as the upper and

inner edge of the iris; in other words, as far as that side of the iris which is nearest the nose. The needle advances nearly to the ciliary ligament, and the surgeon perforates the internal edge of the iris, at its upper part, so that the point of the instrument scarcely appears in the anterior chamber of the aqueous humour, because, that part of the anterior chamber being very narrow, the point of the instrument, how little soever it might advance beyond the iris, would enter the substance of the cornea. The moment the needle appears in the anterior chamber, the instrument must be pressed on the iris from above downward, and from the internal towards the external angle, so as to bring it in a parallel line to the anterior surface of the iris, for the purpose of detaching a portion of the edge of this membrane from the ciliary ligament. This separation being effected, the operator (continues Scarpa) must depress the point of the needle, in order to apply it to the inferior angle of the slit, that he has begun to make. Then the aperture may be enlarged at pleasure, by pushing the iris towards the temple, and withdrawing the needle from before backward, parallel to the anterior surface of the iris, and the greatest axis of the eye. If, when this detachment has been accomplished, no opaque body should appear at the bottom of the eye, the needle is to be withdrawn altogether. If any portion of opaque capsule left behind after the depression, or extraction of the cataract, should afterwards advance, and present itself in the vicinity of the new pupil, the little opaque membrane must be reduced to fragments, and pushed through the artificial opening into the anterior chamber, where, as we have shewn in the article *Cataract*, such membranous portions, or flakes of the capsule, are, in time, dissolved and absorbed with the aqueous humour, which is continually undergoing a renovation.

This separation of the iris from the ciliary ligament, invariably occasions an extravasation of blood, which always renders the aqueous humour more or less turbid; but the turbidness is afterwards absorbed, and the eye recovers its original transparency.

The patient, says Scarpa, complains, during the operation, of a vast deal more suffering, than at the time when he undergoes the extraction or depression of a cataract. It cannot be otherwise; for, in detaching a part of the edge of the iris from the ciliary ligament, some filaments of the ciliary nerves, which proceed to be distributed to the iris, must at least be dragged, or lacerated. However, on the whole, the symptoms consequent to this operation, have neither been obstinate nor fatal in the two cases which Scarpa has

seen. From some experiments made on the dead subject, Scarpa thinks the curved needle, which he uses for the depression of the cataract, would also be better than the straight one for making an artificial pupil; a thing which he intends to ascertain the first favourable opportunity. (*Scarpa sulle Malattie degli Occhi, Capo 16.*)

In the year 1811, the late Mr. Gibson of Manchester published an account of a new method of forming an artificial pupil. It is described as follows: "The first step of the operation is to secure the eyelids, as in the operation for extracting a cataract. A puncture is then to be made in the cornea, with a broad cornea knife, within a line of the sclerotica, to the extent of about three lines. All pressure is now to be removed from the eyeball, and the cornea knife gently withdrawn. The consequence of this is, that a portion of the aqueous humour escapes, and the iris falls into contact with the opening in the cornea, and closes it, like a valve. A slight pressure must now be made upon the superior and nasal part of the eye-ball, with the fore and middle finger of the left hand, till at length, by an occasional and gentle increase of the pressure, or by varying its direction, the iris gradually protrudes, so as to present a bag of the size of a large pin's head. This protruded portion must be cut off with a pair of fine curved scissors, and all pressure at the same time removed: the iris will then recede within the eye, and the portion, which has been removed, will leave an artificial pupil more or less circular." (*Gibson's Practical Observ. on the Formation of an Artificial Pupil, &c. London, 1811.*) Such was this surgeon's mode of operating, when the closure of the pupil was attended with central opacity of the cornea, uncombined with adhesions. The effect of a slight adhesion of the inner border of the iris to the cornea, will be to prevent the protrusion of the first of these membranes through the puncture in the cornea, which protrusion so much facilitates the operation. In this case, a portion, which does not adhere, must be drawn out with a small hook and then removed. Sometimes the adhesion may be separated at the time of making the puncture, and then the iris will protrude. When the whole, or greater part of the inner border of the iris is involved in adhesions to the cornea, these must be separated with the cornea knife after making the puncture, and the iris may then either be drawn out with the hook, or a portion of it be removed by means of very minute scissors. In every case, however, the removal of a portion is essential to success.

When a cataract is known to exist, which it cannot often be, Mr. Gibson re-

commends it to be depressed, or broken to pieces with the needle, before making the artificial pupil; and, when the whole cornea is transparent, he advises forming a flap in the centre of the iris with the cornea knife, and then cutting such flap off with the iris scissors. (*Gibson, Op. cit.*)

In 1812, Sir W. Adams recommended the revival of Cheselden's method of forming an artificial pupil, with the difference of using for the purpose a particular sort of knife. "With a cataract needle (says this oculist) I could not cut through the iris by a gentle force; and, if I ventured to apply a greater force, the iris separated from its attachment to the ciliary ligament, which rendered all further attempts to effect a central aperture useless. The same accident appears to have happened to Mr. Sharp in his trials of this operation. In the hopes of procuring an appropriate instrument, I twice went to London, at the interval of a few months; but, though I described to different instrument-makers the purposes for which it was intended, still I could only procure the needle, which cuts on one edge, and the spear-pointed knife, of different sizes, described by Cheselden. At length, it occurred to me, that the curved edge of the common dissecting scalpel was well adapted to cut with facility. I therefore, when in London, a third time, got a small knife made, two thirds of an inch in length, and nearly a line in width, with a straight back, sharp point, and a curved edge, which cuts back towards the handle for about three lines." (*Adams's Pract. Obs. on Ectropium, &c. p. 30.*) According to this gentleman, in all cases, where there is no crystalline lens, and the cornea is free from opacity, the division of the iris should be made in the centre, and should extend across at least two thirds of its transverse diameter. The eye being gently fixed with a concave sort of speculum, placed under the upper eyelid, the artificial pupil knife is to be introduced through the coats of the eye, about a line behind the iris, with its cutting edge turned backwards. The point is next to be brought forward through the iris, somewhat more than a line from its temporal ciliary attachment, and cautiously carried through the anterior chamber, until it has nearly reached the inner edge of that membrane, when it should be almost withdrawn out of the eye, gentle pressure being made with the curved part of the cutting edge of the instrument against the iris, in the line of its transverse diameter. If, in the first attempt, the iris should not be sufficiently cut, the point of the knife is to be again carried forward, and similarly withdrawn, until the incision is of a proper length. After the operation, the eye is to be covered with a plaster of simple ointment, and the patient put into bed, with

his head raised. (*P. 36—37.*) When the closure of the pupil is attended with a cataract, the primary steps of the operation are the same; but, Sir William Adams takes care also to cut the cataract into pieces, some of which he brings forward into the anterior chamber, while others he leaves in the opening of the iris, where they at first serve as a plug, hindering union by the first intention, (*P. 38.*) and are afterwards absorbed. For an account of this gentleman's particular methods in all the various complications of these cases, the reader must consult the above-mentioned publication. Many successful examples of the operation are there recorded.

That Cheselden's method was undeservedly rejected, there can now be no doubt. Like all other modes of forming an artificial pupil, it cannot be expected to answer in every instance. Besides the authority of Sir W. Adams, we have the testimony of Mr. Ware, to prove, that Cheselden's operation frequently succeeds. This gentleman informs us, that, when the pupil has become closed, after an unsuccessful operation of extracting the cataract, he has in several instances made a new pupil, agreeably to Cheselden's mode of performing the operation, with the most perfect and striking success. "The fibres of the iris retracted as soon as they were divided, and left the pupil very nearly of its natural size. Its shape was not quite round; but, the sight was immediately restored, and to so great a degree, as to enable the patient, by the help of suitable convex glasses, to see distinctly both near and distant objects, neither pain nor inflammation being consequent to the operation."

In a modern work, Professor Maunoir of Geneva, has published a very successful case, in which an artificial pupil was formed, and a caseous cataract extracted. "I operated, (says M. Maunoir) on the right eye in the following manner. The patient being seated on a chair, and having the head inclined upon a cushion, I placed myself behind him, and with the fore-finger of the left hand, confining the upper eyelid, whilst an assistant depressed the lower; I made with the right hand a semi-circular incision in the lower and external part of the cornea. This incision occupied a full third of the circumference of the membrane. On re-opening the eye, the iris was seen projecting a little from the wound in the cornea. I replaced it with the blunt point of my scissors. Introducing the two blades closed into the anterior chamber, and then opening them, I caused the pointed blade to penetrate the iris, leaving the blunt blade between that membrane and the cornea; then closing the scissors, a perpendicular incision of the

iris resulted, describing a little more than half the chord of an arc of two fifths of the circumference of the iris, traced on the side of the temple. The first incision not having occasioned the formation of a pupil of the necessary size, I introduced the scissars into the iris a second time a little obliquely; and immediately the pupil appeared of a satisfactory form and size, but exhibiting the crystalline entirely opaque. The second stroke of the scissars had divided the capsula: I therefore introduced a small curette, in order to endeavour to destroy what adhered of the crystalline to the shrunk and contracted circumference of the old pupil. This attempt did not succeed. Lastly, I effected the passage of a portion of the opaque lens, by means of a slight pressure with a large scoop, exercised on the lower part of the globe of the eye. The crystalline, which was of a cheesy consistence, came out with the greatest ease, and though it was not entirely removed, yet a sufficient quantity was discharged to leave the artificial pupil of a most perfect black. This new pupil was on the side of the temple; and at the exterior and lower part of the iris." (See *Medico-Chir. Trans. Vol. 7, p. 305, et seq.*) In this communication are also two other cases, in which Professor Maunoir operated, with success, though complicated with cataracts, and adhesions of the lens to the iris. In some remarks annexed by Professor Scarpa to the preceding account, the latter expresses his opinion, that it is not necessary to be scrupulous, whether the crystalline be partly, or entirely opaque, whenever the capsule is opaque, and adheres to the iris, behind the edge of the interior and inclosed pupil. "In this case only one remedy can be pointed out, namely, the removal of the opaque adherent capsule, and consequently of the crystalline, whether it be transparent, or opaque. In the second place, (says Scarpa) I think there is no reason to doubt, that, in similar cases, it is advisable to make an incision upon the iris, proportioned to the size of the body to be extracted, rather than to make it small, which obliges the operator to divide the crystalline and the capsule, with the intention of extracting a part, and of abandoning the rest to the powers of absorption. Thirdly; I would establish as a fundamental principle, in similar cases, that, after the complete extraction of the crystalline, with its opaque capsule, by

means of the least possible introduction of instruments, the artificial pupil ought not to be too near the incision in the cornea, and consequently not too near the cicatrix occasioned by it." (P. 317) Scarpa then recommends a particular method of operating, in cases where there are cataracts: after having made, in the manner of Wenzel, a transverse incision in the iris, and in the cornea, he would introduce Maunoir's scissars, blunted at both points, into the anterior chamber of the aqueous humour, and make an incision in the iris, diverging from the cut made with the knife. The aperture thus made, Scarpa thinks would be large enough to allow easy egress to the opaque lens.

Amongst other late opinions, professed by this distinguished surgeon, we find the following: that no instrument is so proper as the scissars for making an incision in the iris; that, when the case is not complicated by cataract, a very small wound in the cornea is sufficient; that the formation of a triangular edge in the iris, by means of a double incision with the scissars, is the most easy and least painful of all the methods hitherto proposed for obtaining a permanent artificial pupil; and, lastly, that spots of the cornea present no obstacle, because it is possible to produce the artificial pupil opposite the transparent part of that membrane. (*Med. Chir. Trans. Vol. 7, p. 320—321.*)

PUS. (from $\pi\upsilon\upsilon\varsigma$, matter.) The fluid formed by the process of suppuration. See *Suppuration*.

R

RACHITIS. (from *ραχις*, the spine of the back, because the disease was once supposed to depend on disease of the spinal marrow.) The rickets. See this word.

RANULA. (dim. of *rana*, a frog.) A whimsical name applied to a tumour under the tongue, arising from an accumulation of the saliva in the ducts of the sublingual gland. The term has either been derived from an imaginary resemblance of the swelling to a frog, or from the disease making the patient, as it were, croak when he attempts to articulate. The writers, who have treated of this disease, before it was known, that the parts affected by it were destined for the secretion of the saliva, have had no accurate notions of its true nature. Celsus has been supposed to have alluded to the ranula, in the fifth section of his seventh book, where, after treating of the diseases of the tongue, he continues with the following passage: *sub lingua quoque interdum aliquid abcedit, quod fere consistit in tunica, doloresque magnos movet.* The latter circumstance, however, renders it probable, that some other affection was alluded to, as a ranula is rather attended with a sense of restraint, than of pain. Various erroneous sentiments were entertained, concerning ranula, by authors, who treated of it subsequently to Celsus. Paré thought it proceeded from an accumulation of a pituitary, cold, viscid matter, which descended from the brain beneath the tongue. Fabricius ab Aquapendente considers the ranula as an encysted tumour of the meliceris kind. Dionis is of a similar opinion. Munick, better acquainted with the modern discoveries of anatomy, does not mistake the nature of the present disease; and he expressly says, that the affection originates from a thick, acrid saliva, which, not being able to pass out of the salivary ducts, accumulates under the tongue, so as to cause a swelling in that situation. Far from adopting the opinion of Munick, Heister fell back to that of Fabricius, and borrows every thing from this author.—Lastly, De La Faye, in his notes on Dionis, has taken up Munick's sentiments; he says, that, "there are two sorts of ranulae; some, which are round, and situated beneath the tongue, seem only to be produced by a dilatation of the excretory duct of the sublingual gland; the others are longer, than they are round; are situated at the side of the tongue, and are formed by a dilatation of the excretory duct of the inferior maxillary gland. The

fluid, which fills such tumours, is the saliva which lodges and gradually accumulates in them, in consequence of its viscosity and the atony of the duct.

The ranula is said to be frequently met with in persons who move their tongue a great deal, and in those who sing. The fluid in the tumour is precisely like white-of-egg; but, it is thicker after having remained a long while in the swelling; it is occasionally of a calcareous, and even stony nature. Modern surgeons are of opinion, that the ranula does not proceed from an inspissation of the saliva, but from an obliteration of the duct, or orifices of this tube. The collection of saliva often produces a tumour of very large size; but, it generally bursts when it has attained the dimensions of a walnut, and then leaves an ulcer, which cannot be healed while the real cause of the disorder remains unknown.

Mr. B. Bell mentions his having seen an ulcer of this kind treated with the utmost care for several months; various detergent and corrosive applications had been employed; and even a mercurial course was resorted to; but all in vain. At length, the true cause of the disease having been ascertained, a cure was accomplished in a few days, by removing a piece of calcareous matter, which by obstructing the ducts, had first caused a swelling, and then the ulceration which ensued.

The edges of the opening very often close again, especially when it has been made with a lancet, and not of sufficient size. In this case, the swelling makes its appearance again, some time afterwards. M. Louis observes, that the ancients have made the same remark; and hence, Paré preferred the actual cautery to the lancet. Dionis also mentions having seen ranulae, which recurred in consequence of a mere opening having been made with a lancet; and he recommends, for the prevention of this, applying a mixture of honey of roses, and vitriolic acid to the inside of the cyst, so as to destroy it. M. Louis remarks, that all authors seem to regret, that the situation of the tumour should prevent the sac from being totally dissected out. The success, which Fabricius ab Aquapendente experienced, when he merely opened the tumour its whole length, did not free him from this prejudice; and Heister says, he should prefer extirpation, if the nature of the adjacent parts, which would be wounded, were not a formidable objection. But, if

this pretended cyst, this pouch, is nothing else than the gland itself, or its duct, dilated by the retention of the saliva, its inside should not be irritated. Whenever a sufficient opening is made, no relapse takes place. Munick particularly advises such an incision, and Rossius mentions the smallness of the opening, among the defects in the treatment, and its being a cause of the disease returning. However, he also recommends destroying the sac; but, specifies for the purpose, only astringent drying applications, which do not act in so powerful a manner.

In a ranula, there is nothing like a cyst which ought to be extirpated. It is enough to lay the cavity open, and occasionally to cut off the edges of the incision, when they will not otherwise unite. M. Louis always observed, that the radical cure depended on a fistulous aperture, through which the saliva continued to flow; and that, when this opening was situated behind the lower incisor teeth, a very annoying ejaculation of the saliva took place, in certain motions of the tongue. This inconvenience must be obviated, to render the cure complete. For this purpose, such an opening for the saliva must be made, as will not close. The perforation of the tumour with the actual cautery, was Paré's method; and thus a durable opening might certainly be obtained, for the excretion of the saliva, in a part of the mouth more backwards, so that patients would be freed from the disagreeableness of continually slobbering, or having their spittle ejected from their mouths in talking.

The ranula, when of long standing, is sometimes so large as absolutely to hinder a person from articulating. M. Le Clerc has recorded a case, in which the root of the swelling extended under the tongue; the tumour filled the whole mouth; the prominence it formed outwardly, was as large as a duck's egg; and the disease, in its progress, had made the teeth of both jaws project outward. At some parts of its surface, a fluctuation was perceptible; other places were exceedingly hard. The patient, who could hardly breathe, demanded assistance: and a puncture was made in the softest part of the outside of the swelling. A thick yellowish fluid issued out of the cannula. The opening was enlarged with a knife; and about a pint of gritty, inodorous matter was extracted. There was no hemorrhage from the cut; and, no sooner had the contents of the swelling been let out, than the patient began to articulate, which he had not been able to do for a long while. The sides of the tumour having been so prodigiously distended, M. Le Clerc thought it proper to destroy the inside of the cavity with a tent, dipped in a mercurial solution. The cure was completed in a month, and the

tongue gradually regained its original size, a part of which it had lost.

But, as M. Louis observes, fortunate as the termination of this case was, it must not be indiscriminately set down, that destroying the cyst, or even opening the tumour, is always requisite. A more simple method will sometimes succeed. In a particular case, which this gentleman has related, a sinuosity, which divided the swelling into a right and left portion, made him suspect that it consisted of two sacs, in contact with each other. On each side, in front, and in the same line, there was a point, which was the orifice of the salivary duct, somewhat dilated, and blocked up with a viscid matter. Having very easily passed a small probe into the orifices, a matter, similar to white-of-egg, made its escape. A small leaden probe was passed into each opening, and, two days afterwards, the sacs were emptied again, and two pieces of lead, somewhat larger, introduced. The man was advised to take out the pieces of lead every morning, empty the swelling, and then replace them. In a fortnight, the openings, having been kept continually dilated, had no tendency to close; the saliva did not accumulate, and the ranulae never appeared again.

In certain cases, the above means are quite inadequate, and the tumour must be totally extirpated. M. Boinet has related, to the French Academy, a case in which the swelling not only filled the whole mouth, but one half of the tumour projected out, and a cure could only be accomplished in the latter manner. The two upper incisor teeth, on the left side, were lodged in a depression observable there; and the canine tooth, of the same side, forced outward by the mass of disease, had pierced the lip near its commissure. A fluid, resembling mucus, flowed from a narrow aperture, at the lower part of the swelling. The tongue could not be seen, so much was it pushed backward; and, for some time, the patient had only subsisted on liquid food, which he was first necessitated to convey to the back of the throat, with some mechanical contrivance. The four incisor teeth, two canine, and first grinders of the lower jaw, had been pushed out of their sockets, by the pressure of the swelling. The patient's aspect was alarming, and he was threatened with suffocation. Extirpation was deemed necessary, and it was performed, with all the caution, which the situation of the tumour demanded. The large cavity thus occasioned, was filled with lint. The lower jaw being found diseased, M. Boinet scraped some of its surface off, and covered the places with lint, either dry, or dipped in spirit of wine. Some exfoliations followed, and the fungous granulations which grew, were repressed with proper applications. In three months,

the parts were healed in so regular a manner, that the motion of the tongue was not in the least obstructed, and no change continued, except the alteration of the voice, occasioned by the loss of teeth. This case is very interesting, and shews how much may be hoped for in difficult cases, from prudent and judicious measures. (See *Encyclopédie Méthodique*; *Art. Grenouillette*, *Mem. de l'Acad. de Chirurgie*, tom. 3. *Sabatier's Médecine Opératoire*, Tom. 2. p. 19, &c. Edit. 2. *Callisen's Systema Chirurgiæ Hodiernæ*, Vol. 2, p. 100, &c. Edit. of 1800. *Lassus, Pathologie Chirurgicale*, Tom. 1, p. 402, &c. Edit. of 1809. *Richter's Anfangsgr. der Wundarzneykunst*, Band. 4, Kap. 1, Edit. of 1800.)

RECTUM. The last large intestine, terminating in the anus, is so named, from an erroneous opinion that it was straight, while, in fact, it is semilunar, being adapted to the concavity of the sacrum.

Piles, which are a disease of the veins of this bowel, are treated of under the term *Hemorrhoids*.

The rectum is also subject to have tumours formed in it. Mr. Hey mentions a young man, who had had, for two years, a swelling in this bowel. The tumour protruded from the anus, whenever the patient went to stool, and generally bled on the same occasion. The disease had been, from the first, attended with pain in the loins. On examination, Mr. Hey found the swelling to be of the size of a nutmeg, adhering to the intestine by a narrow basis. It was firmer in its texture than piles usually are, except when inflamed. The apprehension of a troublesome hemorrhage, led Mr. Hey to prefer tying the base of the swelling to cutting it away, and thus he successfully extirpated the disease. (*Practical Observations in Surgery*, p. 443.)

The *schirro-contracted* rectum is what we have chiefly to consider in the present article. Scirrhus of the rectum is not uncommon at an advanced period of life. Sometimes it extends over a considerable length of the gut, but generally it is more circumscribed. The coats of the bowel become much thicker and harder than in the natural state. The muscular is subdivided by membranous septa, and the internal coat is sometimes formed into hard, irregular folds. The surface of the inner membrane is occasionally ulcerated, so as to form a cancerous disease. Every vestige of the natural structure is sometimes lost, and the gut is changed into a gristly substance. The cavity of the bowel is always rendered narrow at the scirrhus part, and is, sometimes, almost obliterated. When the passage through the gut is very much obstructed, the bowel is always a good deal enlarged just above the stoppage, or stricture, from the accumulation of the feces there. As the disease advances, adhesions form between the rectum and adjacent parts,

and ulcerations produce communications between them.

The disease is usually not much noticed till somewhat advanced, not being at first very painful. The patient only thinks, that he is constipated, and that he voids his stools with a little difficulty. In time, a good deal of pain is felt in the part affected, especially at stool, after which, some relief is experienced. Pus and blood may sometimes be noticed with the excrement, particularly when the disease has advanced to the ulcerated state. The patient at length becomes sallow, the constitution suffers, and dissolution follows. Severe tenesmus attends the whole course of the disease.

Desault has often seen the disease form a communication between the rectum and vagina, and the feces have passed through the latter part. In the latter stage of the affliction, the rectum, bladder, vagina, uterus, and adjacent parts, are all involved in one common ulceration.

When the disease has attained the ulcerated state, it is probably always incurable. Palliatives can now only be resorted to, such as anodyne and emollient glysters, the warm-bath, &c. with the exhibition of medicines like opium, cicuta, uva ursi, &c. Claudius applied his remedies to the inside of the bowel, by means of tents, and did not employ the latter as a mode of curing the disease when less advanced. Valsalva used to introduce a cannula, pierced with numerous holes, when his patient got into the bath, so as to let the fluid enter the intestines. Numerous practitioners, among them Morgagni, made mercurials the base of their treatment, from a supposition that the complaint was of venereal origin.

When the disease is not attended with ulceration, the contraction and thickening of the gut may be diminished by introducing bougies, keeping them for a certain time, every day, so introduced, and increasing their size gradually. The pressure of these instruments seems to lessen the disease, and stop its progress; a proof that its nature differs from that of what is usually understood by scirrhus. Desault used to employ the long tents, made of lint, smeared with cerate, and passed into the bowel by means of a probe, with a forked end. This surgeon gradually increased the size of the tents, so as to continue the compression, to which he conceived all the good was owing. Their length was also augmented, by degrees. Fresh ones were, at first, introduced twice every day. When any hardnesses were situated on the outside of the anus, Desault cured them on the same principle, viz. by making pressure on them, with compresses and a bandage. This eminent surgeon effected a cure of a scirrhus-contracted rectum by this method. The woman was taught to pass occasionally the tents

herself, so as to prevent a relapse. The disease is said to afflict women more frequently than men; from a comparative table kept at the Hôtel-Dieu, this has been the case there in the proportion of ten to one.

A fatal case of mortification of the rectum is detailed by M. Larrey. (See *Parisian Chirurgical Journal*, Vol. 2, p. 398, &c.)

See *Baillie's Morbid Anatomy. Œuvres Chirurgicales de Desault par Bichat*, Tom. 2, p. 422. Also *Observations on the principal Diseases of the Rectum*, &c. by T. Copeland, 1814.

RESOLUTION. (from *resolvo.*) The subsidence of inflammation, without any abscess, ulceration, mortification, &c. Also the dispersion of swellings, indurations, &c.

RETENTION OF URINE. See *Urine*, *Retention of*.

RETROVERSIO UTERI. A turning backward of the womb. See *Uterus*, *Retroversion of*.

RICKETS. (*Rachitis.*) Is mostly met with in young children; seldom in adults. Morrand, however, (*Acad. des Sciences*, 1753,) mentions an instance in which an adult became affected. Pinel has given a description of the skeleton of a rickety foetus, (*Fourcroy's Journal*.) The disease seems to consist of a want of due firmness in the bones, in consequence of a deficiency in the phosphate of lime in their structure. The causes of the affection are involved in great obscurity. Authors have referred them to scrophula, scurvy, lues venerea, difficult dentition, &c.; and Richerand, one of the most eminent surgeons at Paris, still firmly believes, that rachitis is only one of the effects of scrophula in its worst forms. (*Nosographie Chir. T. 3, p. 148. Edit. 4.*)

But these are merely conjectures, which will not bear a rigorous investigation. Professor Boyer in particular has well exposed their invalidity. (*Traité des Mal. Chir. T. 3, p. 611.*)

Rickety subjects are often at the same time scrophulous; and this is, probably, the only reason for scrophula being accounted a cause of the other affection. The particular appearances of rickety children we need not detail, as every one is familiarly acquainted with them: such children are usually of a bad, weak constitution, and their limbs and bones become bent in directions determined by the action of the muscles, and the weight and pressure, which they have to sustain. When the affection is very general, the spine becomes shorter, and is curved in various directions; the breast becomes deformed, not only in consequence of the curvature of the spines, but by the depression of the ribs, and projection of the sternum. The bones of the pelvis fall inwards, and the os pubis generally approaches the sacrum. The latter circumstance is one of the causes of difficult parturition. The clavicles become more bent and pro-

minent forward; the os humeri is distorted outward; the lower ends of the radius and ulna are twisted in the same direction; the thighs are curved forwards, or outwards; the knees fall inwards; the spine and front surface of the tibia become convex; and the feet are thrown outwards.

According to the observations of Mr. Stanley, when the tibia and fibula become curved, they sometimes "acquire increased breadth in the direction of the curve, losing a proportionate degree of thickness in the opposite direction. Hence, the bones become, as it were, newly modelled, passing from the cylindrical into the flattened form. This would seem to be designed for the purpose of enabling them to support more efficiently the weight of the body, since by this alteration they acquire increased breadth and power of resistance in that direction, where the greatest strength is required. I have never noticed (says Mr. Stanley) any expansion in the articular ends of rickety bones, as is mentioned by some authors. I should therefore feel inclined to believe, that there has existed only the appearance of such a phenomenon, the ends of the bones having appeared swollen, in consequence of the emaciation of the surrounding soft parts." (See *Medico-Chirurg. Trans. Vol. 7, p. 402—405.*)

When the thoracic viscera are considerably oppressed by the alteration in the figure of the chest, produced by the rickets, the disease may bring on fatal consequences.

Boyer has thus described the appearances of rickety bones: They are lighter, than natural, and of a red, or brown colour. They are penetrated by many enlarged blood-vessels, being porous, and, as it were spongy, soft, and compressible. They are moistened by a kind of sanies, which may be pressed out of their texture, as out of a sponge, or rather a macerated hide after it has been tanned. The walls of the medullary cylinder of the great bones of the extremities are very thin, while the bones of the skull are considerably increased in thickness, and become spongy, and reticular. All the affected bones, especially the long ones, acquire a remarkable suppleness; but, if they are bent beyond a certain point they break; &c. Instead of being filled with medulla, the medullary cavity of the long bones contains only a reddish serum, totally devoid of the fat, oily nature of the other secretion in the natural state. (See *Boyer's Traité des Maladies Chir. T. 3, p. 619.*) The consistence of several rickety bones, examined by Mr. Stanley, was nearly that of common cartilage. They presented throughout an areolated texture, and the cells were in some parts large, and contained a brownish gelatinous substance. This gentleman did not find the periosteum thickened, as Bichat has described. (*Anatomie Generale, T. 3.*) The investigations of Mr.

Stanley has also discovered, that, in the process, by which ricketty bones acquire strength and solidity, there is always an undeviating regularity in the situation, extent, and direction of the deposited earthy matter. "Thus, it is obvious (says this gentleman) that, in the curved bone, the part where there is the greatest need of strength, to prevent its further yielding, is in the middle of its concavity, or in other words, in the line of its interior curve; and it is just in this situation, that strength and compactness will be first imparted to the bone by the deposition of phosphate of lime. It will be further found, that the greatest resistance being wanted at this part, the walls are accordingly rendered thicker here, than elsewhere, and the degree, to which this excess in thickness is carried, bears an exact ratio to the degree of curvature, which the bone has undergone."

Mr. Stanley's observations also prove, that the bony fibres are arranged obliquely across the axis of the bone, in a direction calculated to augment its strength. Lastly, we learn from the same authority, that if a long bone, like the tibia, be very much bent, while it has to support a great superincumbent weight, the deposition of the bony matter may not be confined to the thickening of the walls of the concave side, but may extend across the medullary cavity, rendering the bone here perfectly solid, and thereby greatly strengthened. (See *Obs. on the condition of the Bones in Rickets, &c.* by E. Stanley, in *Medico-Chir. Trans.* Vol. 7, p. 404, et seq.)

Many infants, which are very ricketty and deformed, improve as they grow up, and their constitutions acquire strength. The deformity of their limbs spontaneously diminishes, and the bones gain a due degree of firmness, resulting from a proper deposition of the phosphate of lime in their texture.

It is a question, whether the restoration of the proper figure of the bones can be promoted by the constant pressure of bandages, and mechanical contrivances, sold in the shops. (See *Distortion*.) Some authors contend, that in very young children machines are useless, as the confinement and inactivity of the muscles, necessarily occasioned by such contrivances, must increase the general debility, and consequently the disease.

Notwithstanding the praises, which have been bestowed on these mechanical means

by their inventors, and even by respectable authors, says Boyer, they are not now used by any enlightened judicious practitioners, it being generally agreed, that it is best to leave to nature alone, aided by good medical treatment, the duty of rectifying bones deformed by the rickets. (*Traité des Mal. Chir.* T. 3. p. 627.) Delpech expresses himself still more strongly against the employment of machinery. (See *Précis Élémentaire des Maladies Chir.* T. 3, p. 740, &c.) These opinions, against mechanical contrivances for ricketty bones, are not meant to apply, however, to machines for rectifying distortions of the foot. In such cases, the malformation does not depend on constitutional causes, and mechanical means will do whatever is possible.

No medicine is known, which possesses any direct efficacy in cases of rickets.—Tonics are indicated, and should be employed. The state of the bowels must in particular be attended to. The disease appearing to consist in a deficiency of lime in the bones, proposals have been made to exhibit internally the phosphate of lime; but, this chemical project has had no success. (See *Bonhomme's Memoir on Rachitis*, and *Duncan's Annals for 1797*.) More good, however, may be effected by keeping children in healthy situations, and in a salubrious air, than by any medicines, whatever. Light, wholesome, nutritious, easily digestible food; cold bathing; good nursing; regular gentle exercise; or airings in a carriage; the use of the flesh-brush, &c. are also highly serviceable. The constitutional treatment of rickets belongs more properly to the physician than the surgeon; and it is not necessary to introduce more of the subject into a Dictionary expressly allotted to surgery.

See the article, *Mollities Ossium*, and consult particularly *Buchner de Rachitide perfecta* *perfecta Disput.* Argent. 1754. *Glisson, de Rachitide, sive, morbo puerili Tractatus*; Lugd. RINGWORM. See *Herpes*.

RUPTURE. A protrusion of the abdominal viscera. A hernia. See *Hernia*.

S.

SABINA. (said to be named from the Sabines, whose priests used it in their religious ceremonies.) Savine. The use of the leaves of this plant, in forming the active ingredient in the ointment commonly preferred for keeping open blisters, we have explained in the article *Blisters*. The other chief surgical use of savine, is as a stimulating application for destroying warts, and other excrescences. For the latter purpose, it is generally powdered, and mixed with an equal proportion of *ærugo æris*. The same powder is also sometimes employed by surgeons for maintaining the hollows into which peas are inserted in issues. The best plan is, first to wet the peas, then roll them in the powder, and put them, in this state, on the issue. But, when the whole surface of the issue has risen high, above the level of the skin, the powder must be sprinkled all over the sore, so as to produce an absorption of the high granulations.—Indeed, even in this manner, a good cavity often cannot be obtained; and, it becomes necessary to destroy the surface of the issue, by rubbing it with the potassa, or potassa cum calce.

SACCHARUM SATURNI. Sugar of Lead. *Cerussa Acetata*. Acetite of Lead. This is very extensively used in surgery, chiefly as a local application to inflamed parts, and in the form of a lotion. See *Inflammation*, *Collyrium*, *Lotio*, *Gonorrhœa*, *Ophthalmia*, and numerous other articles of this Dictionary, for an explanation of the uses of acetite of lead.

SAL-AMMONIAC. *Ammonia Muriata*. *Muriate of Ammonia*. Employed a good deal by surgeons, as an ingredient in discutient lotions. See *Lotio Ammon. Mur.*

SALIVARY FISTULÆ. See *Parotid Duct*.

SANIES. (*Latin*.) A thin, serous matter, discharged from fistulæ, unhealthy sores, &c. It is sometimes tinged with blood.

SAPO TEREBINTHINÆ. (*Starkey's Soap*.) *R.* Kali præpar. calidi ℥j. Olei Terebinth. ℥iij.—The hot kali præparatum is to have the oil of turpentine gradually blended with it, in a heated mortar. Indolent swellings were formerly rubbed with this application, and, perhaps, some chronic affections of the joints might still be benefited by it.

SARCOCE'LE. (from *σαρξ*, flesh; and *κηλη*, a tumour.) A fleshy enlargement of the testicle. (See *Testicle*, *Diseases of*.)

SARCO'MA, or *Sarcôsis*. (from *σαρξ*,

flesh.) A fleshy tumour on any part of the body. (See *Tumours*, *Sarcomatous*.)

SARSAPARI'LLA. The root of sarsaparilla was brought into Europe about 1530. It was at first reputed to possess singular efficacy in venereal cases; but, afterwards lost all its fame. Sarsaparilla was again brought into notice by Dr. W. Hunter, who advised Dr. Chapman to make trial of it in a bad case of phagedenic bubo; and the benefit, obtained in this instance, led Dr. Hunter to extend the recommendation of the medicine. Sir W. Fordyce stated, that sarsaparilla would quickly relieve venereal head-achs, and nocturnal pains, and if persisted in, cure them; that, in emaciated, or consumptive habits, from a venereal cause, it was the greatest restorer of appetite, flesh, colour, and strength, which he knew of; that when mercurial frictions had been previously employed, it would generally complete the cure of the disease of the throat, nose, palate, or spongy bones; and that it would promote the cure of blotches and ulcers, sometimes accomplish it, even without mercury; though, in this circumstance, there was danger of a relapse. Sir W. Fordyce said, sarsaparilla was of little use in chancres; but, when these or buboes, would not heal, after the employment of mercury, it would often cure, and always do good. He allows, however, that, in all venereal cases, sarsaparilla is not to be trusted to, unless preceded by, or combined with, the use of mercury; and he thought sarsaparilla would, probably, always cure what resisted mercury. (*Medical Obs. and Inq. Vol. 1.*)

The celebrated Cullen considered sarsaparilla as possessing no virtues of any kind; for, (says he,) "tried in every shape, I have never found it an effectual medicine in syphilis, or any other disease." (*Mat. Med. Vol. 2.*)

Mr. Bromfield declares, that he never saw a single instance in which sarsaparilla cured the venereal disease, without the aid of mercury, either given before, or in conjunction with it. (*Pract. Obs. on the Use of Corrosive Sublimate, &c. p. 78.*) Mr. Pearson also contends, that sarsaparilla has not the power of curing any one form of the *lues venerea*; but, he allows that it may suspend, for a time, the ravages of that contagion, the disease returning, if no mercury should have been used. This gentleman admits, also, that sarsaparilla will alleviate symptoms derived from the venereal virus. He maintains, that the ex-

hibition of sarsaparilla does not diminish the necessity for giving less mercury. Nocturnal pains in the limbs, painful enlargements of the elbow and knee, membranous nodes, cutaneous ulcerations, and certain other symptoms, resembling venereal ones, are often experienced after a full course of mercury. Such complaints, Mr. Pearson allows, are greatly benefited by sarsaparilla, and exasperated by mercury; and, he observes, that it is from these complaints having been mistaken for venereal ones, that the idea has arisen, that sarsaparilla has cured syphilis, when mercury had failed. Mercury, and the venereal poison, may jointly produce, in certain constitutions, symptoms which are not strictly venereal, and are sometimes more dreadful, than the simple effects of syphilis. Some of the worst of these appearances are capable of being cured by sarsaparilla, while the venereal virus still remains in the system. When this latter disease has been eradicated by mercury, sarsaparilla will also cure the sequelæ of a course of the other medicine. (*Pearson on the Effects of various Articles in the Cure of Lues Venerea*; 1807.)

SCA'LPEL. (from *scalpo*, to scrape.) Originally a raspatory, or instrument for scraping diseased bones, &c. The term now generally signifies a common, straight, surgical knife.

SCA'RIFICATION. (from *scarifico*, to scarify.) The operation of making little cuts, or punctures, in a part, for the purpose of taking away blood, letting out fluid in anasarca cases, or air, in instances of emphysema.

SCIRRHUS; SCIRRHOMA; SCIRRHOSIS. (from *σκιρρω*, to harden.) The etymological import of these terms seems merely to be any induration. The first is now generally restricted to the induration, which precedes cancer, in the ulcerated state.

SCLERIASIS; SCLEROSIS. (from *σκληρυνω*, to harden.) A hard tumour, or induration.

SCRO'PHULA, or SCROFULA. (from *scrofa*, a sow.) So named, because swine are said to be subject to it. Called also, *struma*, and the *King's evil*. A disease, one of the chief, or most palpable symptoms of which is a chronic swelling of the absorbent glands, in various parts of the body, which glands tend very slowly to a state of suppuration, that is almost always imperfect. Our notions of scrophula, however, would be very imperfect, were we to define the disorder to be a morbid state of the lymphatic glandular system. The first appearances, indeed, frequently consist of spots on different parts of the body, and of eruptions and ulcerations behind the ears. As a judicious author remarks, the system

of absorbent glands, it is true, seldom, or never fails to become affected in the progress of the disease; but, there is reason to believe, that scrophula frequently appears, for the first time, in parts, which are not of a glandular nature. There are, perhaps, but few, if any, of the textures of the human body, or of the organs, which these textures form, that are not liable to attacks of scrophula, and to scrophula as an original idiopathic affection. (*Thomson's Lectures on Inflammation*, p. 134.)

Scrophula generally shews itself during infancy, between the age of three and seven; sometimes rather sooner; but, frequently, as late as puberty, and, in some instances, though a very few, not till a much more advanced period of life. In the latter cases, the disease is said to be rarely so complete, or well marked, as it is in young subjects.

It seldom attacks the glands in children under two years of age, though Dr. Thomson has seen it occur earlier than this. Dr. Cullen used to mention a case, in which the disease broke out in an infant only three months old; but, says Dr. Thomson, this is an uncommon event. But, though glandular scrophula occurs most frequently in children, it is by no means confined to that period of life. Dr. Thomson has even found the lacteal glands affected with scrophulous inflammation in persons of very advanced age. (*Lectures on Inflammation*, p. 136.) Probably, however, such patients had laboured under scrophulous complaints in their earlier days.

Scrophula is also as hereditary as any disease can be; that is to say, it is so as far as any particular kind of temperament, or constitution, can descend, more or less completely, from parents to children. Mr. White, in his treatise on struma, has strongly censured calling the disease hereditary; but, his observations only lead to these conclusions, that children, born of scrophulous parents, are not invariably affected with scrophulous diseases; and that, sometimes, one child has some strumous affection, while the parents, and all the rest of the family, have no appearance of scrophulous habits. However, I should conceive, that neither Mr. White, nor any other writer will maintain the opinion, that scrophula does not much more frequently afflict the children of scrophulous parents, than the offspring of persons, who have always been perfectly free from every tendency to any form of this affliction. Too numerous are the facts which occur to my own mind, to allow me to entertain the smallest doubt, that scrophula runs very much in certain families. In this sense, I think the term *hereditary* perfectly accurate and allowable. But,

at the same time, I beg the reader to understand, that I have no intention of questioning what seem to be irrefragable truths, viz. that the children of scrophulous parents often continue, as long as they live, entirely free from the disease; and that one child is sometimes afflicted, while its father, mother, brothers, sisters, and all the rest of its relations, have never had any tendency to strumous disorders.

When scrophula does not actually take place at a very early period of life, it is generally stated by writers on the subject, that the particular constitutions, in which there is a disposition to the disease, are, in a certain degree, distinguishable. In the individuals, possessing the disposition in question, a peculiar softness and flaccidity of fibre are remarkable; their hair is more frequently light coloured than dark; and their eyes are said to be more often of a blue, than any other colour. Their skin is generally very fine, and even handsome, both in regard to its outward texture, and complexion. Subjects with scrophulous constitutions frequently have a kind of thickening of the upper lip; this swelling is sometimes very considerable, and occasionally extends as far as within the nostrils. Scrophula is also very often complicated with rachitis, or follows the latter affection; but, there is as little reason for supposing rickets to arise from scrophula, as this latter from rickets. In some instances, however, the complexion is dark, and the skin coarse; but, in these subjects, at least when young, the face is generally tumid, and the look unhealthy. (*Burns on Inflammation, Vol. 2, p. 232.*)

In many instances, the last joints of the fingers have been observed to be enlarged, and the belly is generally larger, than usual. (*Thomson, p. 134.*)

Mr. White seems, as I think, with some appearance of truth, to deny that grey, or blue eyes, light hair, and a fair complexion, ought to be considered as marks of a scrophulous predisposition; for, the majority of children in this country have light hair, and eyes, while young, which become darker as they advance in life. Now, as the majority of scrophulous patients are children, and young subjects, and as most children in this country have naturally the kind of hair and eyes above described, it seems inaccurate to lay any stress on persons affected with struma, or predisposed to this disease, having such appearances. (*See White on the Struma or Scrophula, p. 38. Edit. 3.*)

Dr. Thomson expressly declares, that some of the worst cases of scrophula, which he has seen, occurred in persons, whose complexion and hair were of a very dark colour. (*Lectures, p. 134.*) Another

fact, which I think tends to impeach the accuracy of the common doctrine about complexion, is the circumstance of so many negroes being afflicted in this country with scrophula in its worst forms. Does not this fact indicate, at the same time, that it is climate, which is most powerfully concerned in the production of the disease; since the African black, in his own country, is nearly exempt from scrophula?

I believe the fact is now almost generally admitted, that females are rather more subject, than males, to scrophulous disease.

Struma, according to Mr. White, is as universal a complaint as it is ancient; but it prevails more extensively in temperate latitudes, than in very hot or very cold climates. It is also more frequent in some parts of Europe than others; and, in this country, it has been found to be most general in the counties of Suffolk, and Lancashire. At all periods, it seems to have been a very common complaint in this island. From history, we learn, that it was denominated the king's evil in the time of Edward the Confessor, who is supposed to have been the first that attempted to cure it by the royal touch. From a register kept in the royal chapel, we find that Charles the Second touched 92,107 persons, in a certain number of years; and this equally bigoted and useless practice was not discontinued till a recent period, when kings were found to be, as well as their poorest subjects, totally destitute of all supernatural power.

Scrophula is not communicable from one person to another; neither can it be conveyed into the system by inoculation. The opinion also, that scrophulous nurses may infect children, seems also to rest on little foundation. (*See White, p. 56, 57.*)

The parts, which are most frequently affected by scrophula, next to the lymphatic glands, are the spongy heads of the bones, and the joints. The form, which the disease assumes in the latter situations, is particularly described in the article *Joints*. The disorder of the spine, attended with a paralytic affection of the lower extremities, is, no doubt, very frequently of scrophulous origin. (*See Vertebrae.*) The spina bifida is a congenital disease, which is found to occur most frequently in children, whose parents are scrophulous. (*Thomson's Lectures, p. 133.*) The abscess, which forms in the cellular substance, between the peritoneum and psoas muscle, is often regarded as a strumous disease; and when the contents of the abscess are found to contain flakes of a curdy matter, somewhat resembling white-of-egg, a substance peculiar to scrophulous abscesses, no one can doubt, that the complaint is connected with this constitutional affec-

tion. (See *Lumbar Abscess*.) The chronic enlargement of the thyroid gland, is by many considered as scrophulous; and, the opinion seems to be strengthened by the fact, that patients, with this affliction, very often have, at the same time, other complaints, which are unequivocally strumous. It might also be noticed, that this enlargement of the thyroid gland most frequently commences at an early period of life, like other scrophulous diseases; and, like them, is benefited by the carbonate of soda. (See *Bronchocele*.) Scrophula also frequently makes its appearance in the form of imperfect suppurations, in various parts of the body; the contents of such abscesses being a curdy kind of matter, and the skin covering them, having an unhealthy red appearance, and a thickened doughy feel. The mesenteric glands are particularly often found universally diseased, and enlarged in scrophulous subjects; and, as all nutriment has to pass through these parts, before it can get into the circulation, we cannot be surprised at the many ill effects which must be produced on the system, when such glands are altered, and, no doubt, obstructed, in the way in which they frequently are. Scrophula also frequently makes its attack on the testicle. (See *Testicle, Diseases of*.)—The female breast likewise not unfrequently becomes affected with scrophulous tumours, and abscesses.

Dr. Thomson believes, that more or less local inflammation occurs in every form and stage of scrophulous diseases. He observes, that the swellings are very often from the first attended with a sensible increase of heat and redness, and that the pain, though seldom acute, is always present in a greater or less degree. Pressure on scrophulous swellings never fails to create pain; and the temperature of the skin covering them, is usually two or three degrees higher, than that of the contiguous parts. (*Lectures, &c. p. 131.*)

The scrophulous inflammation (says Mr. Burns) is marked by a soft swelling of the affected part, which, very frequently is one of the lymphatic glands. The covering, or coat of the gland, becomes slightly thickened, and its substance more porous and doughy. The swelling increases, and the doughy feel changes by degrees into that of elasticity, or fluctuation, and a firm, circumscribed, hardened margin, can be felt round the base of the tumour. The skin is slightly red. If, at this time, an incision, or puncture, be made, either no matter, or very little, is evacuated, the lips of the wound inflame and open, displaying a sloughy-looking substance within; and, betwixt this and the skin, a probe can often be introduced for some way all round. If, however, the disease should have advanced further, then there

is very little elasticity in the tumour; it is quite soft, rather flaccid, and fluctuates freely; the skin becomes of a light purple colour, and small veins may be seen ramifying on its surface. Some time after these appearances, the skin becomes thinner at one particular part, and here it is also generally rendered of a darker colour. It afterwards bursts, and discharges a thin fluid, like whey, mixed with a curdy matter, or thick white flocculi. The redness of the skin still continues; but the aperture enlarges as the tumour subsides, and thus a scrophulous ulcer is produced. The margins of this kind of sore are generally smooth, obtuse, and overlap the ulcer; they are of a purple colour, and rather hard, and tumid. The surface of the sore is of a light red colour; the granulations are flabby and indistinct, and the aspect is of a peculiar kind, which, says Mr. Burns, cannot be described. The discharge is thin, slightly ropy, and copious, with curdy flakes. The pain is inconsiderable. When this ulcer has continued for some time, it either begins slowly to cicatrize, or, as more frequently happens, the discharge diminishes and becomes thicker. An elevated scab is next formed, of a dirty white, or yellowish colour. This continues on the part a good while; and when it falls off, leaves the place covered with a smooth purple cicatrix. Mr. Burns adds, that the preceding description corresponds to the mild scrophula, or the *struma mansueta*, of the old writers. This gentleman next remarks, that, occasionally, especially if a bone be diseased below the ulcer, the sore has a more fiery appearance, the surface is dark-coloured, the margins soft, elevated, and inflamed, and sometimes retorted. The discharge is watery, the pain very considerable, and the surrounding skin inflamed. This has been called the *struma maligna*. Such overacting scrophulous sores are most frequently met with over the smaller joints, particularly those of the toes. (*Burns*.) Sometimes a scrophulous abscess, after it has burst, forms a sinus; the mouth of which ulcerates, and assumes the specific scrophulous appearance, while the track of the sinus still continues to emit a discharge. Mr. Burns also remarks, that scrophulous swellings are often disposed to subside in winter, and recur on the approach of summer; but, he adds, that this is not an invariable law. The glandular enlargements are very apt to become smaller, in a short time, in one place, while other glandular swellings originate with equal suddenness, somewhere in the vicinity of the former ones. Ulcers, also, very often heal, upon the appearance of the disease in other parts. (See *Dissertations on Inflammation, by John Burns, Vol. 2, 1800.*)

The glandular swellings, which occur in

syphilis, says Dr. Thomson, are of a more acute character, than those, which proceed from scrophula. They arise from the absorption of a specific poison; and they do not, like those of scrophula, admit of a spontaneous cure. Chronic swellings of the lymphatic absorbent glands occur also in carcinoma; but, these manifest little, or no disposition to suppuration; they succeed most frequently to carcinomatous indurations, or ulcers, existing in the neighbourhood of the glands affected; and they are accompanied in their progress and growth by a peculiar lancinating pain. (See *Thomson on Inflammation*, p. 135.)

With regard to the proximate cause of scrophula, medical men may be said to remain, even at the present day, in entire ignorance. Of the exciting causes, very little is also known. Mr. John Hunter remarks, that "in this country, the tendency to scrophula arises from the climate, which is in many a predisposing cause, and only requires some derangement to become an immediate cause, and produce the whole disease." (*Treatise on the Venereal Disease*, p. 26.) In the same part of the work, this celebrated writer takes notice of slight fevers, colds, small-pox, and measles, exciting scrophulous diseases. He observes, also, that, in particular countries, and in young people, there will sometimes be a predisposition to scrophula: and that, in such subjects, buboes will more readily become scrophulous. (P. 27.) In short, it was one of Mr. Hunter's opinions, and probably a most correct one, that the venereal disease is capable of calling into action such susceptibilities as are remarkably strong, and peculiar to certain constitutions and countries; and that, as scrophula is predominant in this country, some effects of other diseases may partake of a scrophulous nature. (P. 96.) Mr. Hunter, speaking of venereal buboes, mentions his having long suspected a mixed case, and adds, "I am now certain that such exists. I have seen cases, where the venereal matter, like a cold, or fever, has only irritated the glands to disease, producing in them scrophula, to which they were predisposed. In such cases, the swellings commonly arise slowly, give but little pain, and seem to be rather hastened in their progress, if mercury is given to destroy the venereal disposition. Some come to suppuration while under this resolving course; and others, which probably had a venereal taint at first, become so indolent, that mercury has no effect upon them; and, in the end, they get well of themselves, or by other means." (P. 269.) For such buboes, Mr. Hunter used to recommend sea-bathing; and, in case of suppuration, poultices made with sea-water.

In the words of a well-informed Professor, scrophula readily forms an alliance

with almost every morbid affection, occurring either from external injury, or from internal disease; it modifies the appearance of other diseases, and seems to convert them gradually into its own nature. Indeed, there are few of the local inflammatory affections, which occur in this country, in which the symptoms and effects of these affections, and the operation of the food and remedies employed for their cure, are not more or less modified by the degree of scrophulous diathesis, which prevails in the constitution of those who are affected by them. The scrophulous diathesis, wherever it exists, usually gives more or less of a chronic character to local inflammatory affections.—(*Thomson's Lectures*, p. 131.)

It would be tedious and useless to expatiate on the many absurd notions, which have been entertained, concerning the proximate cause of struma. All that we need add in this work, is, that certain constitutions probably have a congenital disposition to the disease; that such disposition may probably be increased, or diminished, by the operation of climate, mode of life, age, &c.; and that irritations of a thousand kinds may excite the disease into action, when the system is predisposed to it, by inexplicable causes. That climate has great influence, cannot be doubted, when we reflect, that the inhabitants of certain countries, in which the temperature is invariably warm, never suffer from scrophula. There can also be no doubt that, with age, the disposition to scrophula diminishes; for, children, much afflicted while young, frequently get quite well when they approach the adult state; and, if a person has remained perfectly free from any mark of a scrophulous constitution, till the age of twenty-five, he may be considered as nearly out of all danger of the disease.

TREATMENT OF SCROPHULA.

"For the cure of scrophula, (says the celebrated Cullen,) we have not yet learned any practice that is certainly, or even generally successful. The remedy which seems to be the most successful, and which our practitioners especially trust to, or employ, is the use of mineral waters. But, (adds this eminent physician,) in very many instances of the use of these waters, I have not been well satisfied, that they had shortened the duration of the disease more than had often happened when no such remedy had been employed. With regard to the choice of the mineral waters most fit for the purpose, (says Cullen,) I cannot, with any confidence, give an opinion. Almost all kinds of mineral waters, whether chalybeate, sulphureous, or saline, have been employed for the cure of

scrophula, and, seemingly, with equal success and reputation; a circumstance, which leads me to think, that, if they are ever successful, it is the elementary water that is the chief part of the remedy. Of late, sea-water has been especially recommended, and employed; but, after numerous trials, I cannot yet discover its superior efficacy." (*First Lines of Physic*, Vol. 4.) On the subject of mineral waters, Dr. Thomson very properly remarks, that they are now usually employed as purgative and tonic remedies, and not as specifics. In employing them it is often difficult to distinguish between the effects, which they in reality produce, and those which are to be attributed to the slow operation of time, the season of the year, change of situation, alteration in the mode of life, or exercise in the open air. (*Lectures on Inflammation*, &c. p. 195.)

Dr. Fordyce extolled bark for its efficacy in scrophulous diseases; he endeavours to prove, that, in cases of tumefied glands, attended with a feeble habit, and a weak circulation, it is a most efficacious medicine, and acts as a resolvent and discutient. He also brings forward a case, in support of bark being a means of cure for the ophthalmia strumosa. (See *Med. Obs. and Inq.* Vol. 1. p. 184.) Dr. Fothergill, in the same work, p. 303, writes in favour of the good effects of bark in similar cases; the latter sometimes gave, at the same time, small doses of calomel.

Dr. Cullen considered the efficacy of bark in scrophula as very dubious and trivial. (*First Lines*, &c. Vol. 4.)

Mr. Burns remarks, that bark has been frequently found useful in the cure of scrophulous inflammation, but more often of ulceration, than tumefaction of the glands. But, adds this gentleman, it does not appear to possess, by any means, that certain power of curing scrophulous affections, which is attributed to it by Dr. Fothergill and several other authors. He observes, that we are not to suppose, that it will infallibly cure scrophulous inflammation, or ulceration of parts, which, even when affected with simple inflammation, are very difficult of cure. If it be difficult to cure a simple inflammation, or ulceration, of a tendon, cartilage, or bone, we must not be disappointed if even a specific remedy for scrophula (were such ever discovered) should prove ineffectual in procuring a speedy restoration to health. Mr. Burns contends, that bark is often ineffectual, because improperly administered. Given in small quantities, once or twice a day, it may prove a stomachic, and increase, like other tonic bitters, the power of the stomach, or the functions dependent on it; but, in order to obtain the benefits of the specific action of bark, he maintains, that it should be

given in large quantities, for several weeks, with a good diet, air, and proper exercise.—(*Dissertations on Inflammation*, Vol. 2. p. 371.) Dr. Thomson does not believe, that bark, or iron, has any specific virtue in curing scrophula; but, he admits, that either of these medicines may sometimes prove useful in improving the tone of the digestive organs, when given after, or occasionally along with, a course of purgative mineral waters. (*Lectures*, p. 197.)

As far as I can judge, Mr. White has, with much reason, recommended paying attention to such circumstances as may have effect in preventing the disease, viz. air, cleanliness, exercise, and diet. He mentions cold-bathing among the preventives of struma, and speaks of sea-bathing as being the best. He advises attention, also to be paid to the manner of clothing children, keeping them more covered in winter, than summer. Mr. White thought, that allowing children to sleep a great deal was prejudicial; but, this seems to me only conjecture.

In noticing the treatment of the disease, Mr. White states, that "the general idea of the struma is, that it is a disease of debility; and therefore, the great object is, to invigorate the habit by every possible means; the chief of which are tonic medicines, and sea-bathing. Some are of opinion, that in the case of young patients, this should be continued, during the summer months, every year, to the age of fourteen or sixteen. Many recommend it, not only in the summer, but throughout the year: whilst others are for administering alteratives, principally the alkaline salts, with or without antimonials, and the different tonics, during the winter; and the sea-water, and sea-bathing, or cold-bathing, during the summer, for a continuance of two or three years from the commencement of the disease; with this general observation, that they will outgrow the complaint." Mr. White adds, that the chief external means are fomentations of sea-water, and cataplasms, made with the same. With respect to regimen, some recommend a milk and vegetable diet; others animal food, and fermented liquors.

Mr. White maintains, that the preceding plans of treatment are not, in general, efficacious, though in some instances, they may prove useful. "In early affections of the lymphatic glands, (says this gentleman,) and from the want of a pure air, and proper exercise, where children are delicate and irritable, a change of situation to the sea-side, together with bathing, when they have acquired some strength, must be exceedingly proper; and, in gross plethoric subjects, who have diseased lymphatics, from improper feeding, and want of necessary exercise, a journey to the sea-coast may be very use-

ful, particularly if the salt-water is drank often, and in a sufficient quantity to become purgative. This, with the novelty of their situation, which may naturally produce an increase of exercise, might answer every expectation; but, these are the kind of cases that, with a very little attention, are easily cured." (*White on the Struma*, Edit. 3. p. 104.)

The conclusion to which Mr. White's remarks upon this part of the subject tend, is, that sea-bathing only deserves praise, as a preventive, and in the early stages of the disease. He particularly condemns cold-bathing, for poor, weakly, debilitated children, whose thin visage, enlarged belly, and frequent tickling cough, sufficiently indicate diseased viscera; such do not recover their natural warmth, after cold-bathing, for hours, and their subsequent head-ach, livid lips, and pale countenance, are sufficient marks of its impropriety. (P. 107.)

Dr. Cullen entertained a very favourable opinion of cold-bathing, since he affirms, that he had seen scrophulous diseases more benefited by it, than any other remedy. (*First Lines of Physic*, Vol. 4.)

"Cold-bathing, especially cold sea-bathing (says Mr. Russell) is a remedy universally employed in scrophula, and I believe with great advantage in many cases; for it not only appears to improve the patient's general health and strength, but likewise to promote the detumescence of enlarged glands, and the resolution of indolent swellings in the joints, even after they have attained a considerable size, and have existed for a great length of time. But, in order that cold-bathing may be practised with safety, and advantage, the constitution must have vigour to sustain the shock of immersion without inconvenience. If the immersion be succeeded by a general glow over the surface of the body, and the patient feels cheerful, and has a keen appetite, we may conclude that he agrees with the cold bath; but if he shivers on coming out of the water, continues chill, and becomes drowsy, we may be assured that the practice of cold-bathing does no good, and had better be omitted.

"In estimating the comparative merit of cold-bathing and warm-bathing, in the cure of scrophulous complaints, my own experience, together with the result of different conversations on the subject with some of the most judicious practitioners of my acquaintance, would lead me to bestow much more commendation on the effects of warm-bathing. I should not even be inclined to circumscribe the practice to cases of emaciation and debility, since from observation, I am fully satisfied with regard to the beneficial effects of the warm bath to patients of plethoric constitu-

tions, who were much affected with swelled scrophulous glands. Several of those instances occurred in young women, about the prime of life, who were in all respects healthy and vigorous, abating the swellings of the glands, and those symptoms of distress which were connected with fullness of blood.

"The sensation of the warm bath is exceedingly grateful to most patients, and the practice is universally safe. It may be employed at all seasons of the year, and in all weather, without danger or inconvenience; the risk of suffering from exposure to cold, immediately after immersion in the warm bath, having been much magnified by prejudice. There is not even any good reason to believe in the existence of such a risk. The precautions, however, which are employed to avert it, are perfectly innocent; and provided they do not impose any unnecessary and incommoding restraints upon the practice, may be encouraged, so far as to relieve the patient's mind from uneasiness and groundless apprehensions.

"It requires many weeks, and sometimes several months, to ascertain the full effects of warm-bathing in relieving scrophulous complaints; but, as the practice is not attended with any inconvenience, nor followed by any bad consequence, there can be no reason to intermit the course, till the trial is completely satisfactory: and I am convinced, that the practice of warm-bathing, in cases of scrophula, will be more universally adopted, after the knowledge of its beneficial effects is more widely diffused." (See *Russell's Treatise on Scrophula*.)

Nothing can be more satisfactory (says Professor Thomson), than the evidence, which is on record of the efficacy of the muriate of soda, as it exists in sea-water. In reading this, one only wonders how so efficacious a remedy should ever have fallen into neglect. (P. 196.) In a subsequent passage, however, the same gentleman evinces only a limited confidence in this means of relief. "Local sea-bathing, both cold and warm, has often appeared to be of use in procuring the resolution of scrophulous swellings. The temperature of the bath must always be varied according to circumstances, according to the season of the year, the strength and habits of the patient, (and the particular effect, which the bath seems to produce. It is at all times difficult to distinguish between the effects immediately arising from the application of salt water to the body, and those which arise from the increased warmth of temperature in the bathing seasons of the year; from the exercise, which patients going to sea-bathing generally take in the open air; from the change of situation and amusements; and, among the poorer classes,

from the more nourishing diet and exemption from labour, in which they are usually permitted to indulge, during their residence at sea-bathing quarters. It is not improbable, that those living on the sea-coast, who become affected with scrophula, would, for similar reasons, derive equal benefit by going from the sea-coast to reside for a time in the interior of the country." (See *Thomson's Lectures*, &c. p. 203—204.)

With regard to electricity, Mr. White thinks it useful, when from length of time the enlarged glands have acquired a degree of hardness and insensibility.

Mr. White, after enjoining attention to air, exercise, and diet, as promotive of a recovery, as well as preventive of the disease, proceeds to explain his own practice. The internal cases, which properly belong to the physician, we shall dismiss from consideration. The first external symptoms, such as swellings of the lips, side of the face, and of glands under the chin, and round the neck; also other symptoms, usually considered as strumous, viz. roughness of the skin, eruptions on the back of the hand, and different parts of the body, redness, and swelling of the eyelids, and eyes; are accompanied, according to Mr. White's conceptions, with an inflammatory diathesis, though seldom such a one, as to require bleeding. Calomel is the medicine, which this gentleman recommends for the removal of the foregoing complaints. It is not to be given in such quantities, as to render it a powerful evacuant, either by the intestines, or any other way; but, in small doses, at bedtime. Thus, says Mr. White, "it remains longer in the intestinal canal, a greater quantity is taken into the habit, and the patient is less susceptible of cold, than when taken in the day-time. The first, and, perhaps, the second dose may prove purgative, which is, in general, a salutary effect; but, afterwards, the same quantity will seldom do more, than is sufficient to keep the body open; and should it fail of answering that purpose, I have usually recommended some gentle purgative, every third or fourth morning, according to circumstances. If there should be a prevailing acidity, a few grains of the sal sodæ, magnesia, or some testaceous powder, may be added to the medicine. By this simple method (continues Mr. White) most of the symptoms before-mentioned, will, in a short time, disappear; but if the tumours should continue hard, and retain their figure, without dividing into smaller ones, we may derive some benefit from external applications, particularly the steam of warm water. I have used a variety of medicinal

herbs with success; but am inclined to believe, that the advantage was principally derived from the warm water, &c. At other times, I have stimulated the part affected by electricity, insulating the patient, and drawing sparks from the tumour, until a slight degree of inflammation was excited. After the application of the steam, or the use of the electrical machine, I have sometimes rubbed a little of the unguentum mercuriale into the tumour, and neighbouring parts, or applied the emplastrum saponaceum, or mercuriale cum ammoniaco, over the swelling, or a liniment with camphor, ol. olivarum, and sp. terebinth." Mr. White adds, that in such cases, if the tumours should suppurate, and burst, the parts will, in most instances, heal without much trouble. For eruptions on the head, he recommends applying the ung. saturn. album camphoratum, or the cerat. alb. cum hydrarg. præcip. alb. For the roughness of the skin, which is generally followed by eruptions, he also advises the aqua-vegeto-mineralis, aqua calcis, solutions of sal. tartar. or of the hydrarg. mur. as outward applications. "This last (says Mr. White) will seldom fail to check the progress of the complaint, and dry the sores; and in the quantity of ten or twelve grains, to a quart of warm water, the use of it will not be productive of any pain. If the eruption should ulcerate, and require any unctuous application, to prevent the adhesion of the linen, the ointment before-mentioned may be applied; the best remedy will be warm-bathing, and when practicable, the sea-water claims a preference." (P. 114.) The author next mentions his having occasionally recommended the vinum antimoniale, tartarum emeticum, decoctum Lusitanicum, decoctum lignorum, or sarsaparillæ; and that he sometimes found advantage derived from artificial drains. We need not detail this gentleman's mode of treating affections of the eyelids, as the reader may find all the necessary instruction, concerning scrophulous diseases of the eye and eyelids, by referring to *Ophthalmia* and *Psorophthalmia*.

For the cure of indurations in the breast, remaining after mammary abscesses, Mr. White speaks very highly of the effects of the steam of warm water; and cautions us against indiscriminately employing calomel, which will often affect the mother little, but the child violently. Mr. White mentions his employing a small tin machine, large enough to hold a pint and a half, or two pints of boiling water. From the top proceeded a narrow tube, ten, or twelve inches long, through which the steam passed. Near its end, which was moveable and curved, was a joint, for the greater con-

venience of directing the steam to the diseased parts. The water was easily kept boiling, by means of a lamp under the machine. Mr. White says, that the steam should be employed twice, or thrice a day, and a piece of flannel, or skin, afterwards applied. The body should also be kept open. In obstinate, neglected cases, mercurial preparations, according to Mr. White, must likewise be given, and, if they affect the child much, suckling should be suspended. (P. 117, 118.)

Mr. White speaks largely of the treatment of cases, in which the mesenteric glands are diseased; but, this subject strictly belongs to the physician. When, in these instances, the glands of the neck, or other parts of the body, tend to a state of suppuration, it is very slowly, the skin appearing uniformly thin, and of a deep red colour, and the tumour seeming flaccid. In such cases, Mr. White recommends the use of the lancet or caustic; for, if no artificial opening is made, it will be a long time, before the skin gives way; and, when it does, the aperture will not only be very small, but often unfavourable in its situation. Mr. White adds, that the contents will often be more like mucus, than pus, or like a mixture of both; and the discharge will continue for a great length of time, if no remedy is applied. This gentleman mentions his having found a solution of gum myrrhæ in aqua calcis, used as a lotion, and the ceratum saponaceum, or some similar outward application, the best method of treating this symptom.

We need not describe Mr. White's practice in the treatment of scrophulous joints, as the subject is fully considered in the article *Joints*. It appears, however, that he confirms the efficacy of stimulating applications, and pressure with bandages, when the fingers and toes are affected with strumous disease. (P. 143.)

Dr. Crawford, M. Pinel, and others, have tried the muriated barytes, as a remedy, in scrophulous cases. (*Med. Communications, Vol. 2. Nosographie Philosophique, Vol. 2. p. 238.*) It had the recommendation of the celebrated Hufeland. Mr. Burns says, that the muriate of barytes has no effect on diseased glands; but, that it is occasionally serviceable in scrophulous ulceration, though, he adds, that it deserves little dependence. (*Dissert. on Inflamm. Vol. 2. p. 372.*) This gentleman recommends the following formula: *R. Terræ Ponder. Salit. Chryst. gr. x. Aq. Font. Aq. Cassiæ, utriusque, ℥iij. Syrup. Aurent. ℥ij.* Half an ounce of this may be given at first, twice or three times a day, and gradually increased to such quantity, as the stomach can bear without sickness.

At present, few practitioners have any faith in the antiscrophulous virtues of the muriate of barytes; and, as Dr. Thomson remarks, it has had a much shorter-lived reputation, than sea-water, or its successor the muriate of lime. (See *Lectures on Inflammation, p. 196.*)

Fourcroy proposed trying the muriate of lime; but, its efficacy is very doubtful, and inconsiderable. "Professor Thomson (says Mr. Russell) has favoured me with the following observations on the effects of muriate of lime. He employed muriate of lime in various cases of scrophula, without having derived benefit from it in a single instance. Some patients, indeed, he admits, got well, while under a course of muriate of lime; but then he had no reason to ascribe the cure to the effect of the medicine. In other cases, on the contrary, the muriate of lime produced severe sickness and oppression at the stomach, and the patients got daily worse, till the muriate of lime was intermitted, and other medicines employed. The relief, experienced from the intermission of the muriate of lime, left no doubt, with regard to the injurious effects, which the use of it had produced; and from extensive experience and accurate observation on the subject, Professor Thomson is satisfied, that muriate of lime is attended with prejudicial effects in many cases of scrophula." (See *Russell's Treatise on Scrophula.*) Since the publication of the last edition of this dictionary, I have seen the muriate of lime given in several cases of scrophula; but, without any beneficial effect on the disease. How long the muriate of lime will be permitted to enjoy its present fame, Dr. Thomson will not venture to say; but from what he has seen of its use, he imagines, its reputation will only last, till some other new remedy is proposed by those, who are still sanguine in their hopes of discovering a specific for scrophula. (*Lectures, &c. p. 196.*) Iron, given either alone, or joined with the fixed, or volatile alkali, also deserves very little confidence. Burnt sponge, millipedes, and sulphate of potassa, have all been extensively tried: the first of these is, in my opinion, sometimes useful in diminishing enlarged scrophulous glands: that it has this effect on bronchoceles, is indisputable.

The Marischal de Rougeres employed a remedy, composed of iron filings, muriate of ammonia, kali præparatum, &c. (*Journ. de Med. tom. 40. p. 219.*)

Several narcotics have been tried, such as opium, hyoscyamus, the solanum dulcamara, &c.; but, though their virtues against scrophula have been sometimes cried up very highly, the moderns have lost all faith in them. The attention of

the public to the effects of cicuta, in cases of cancer and scrophula, was first particularly excited by the accounts of its virtues published by Baron Stork.

Fothergill also praises cicuta, and, perhaps, it is as good an internal medicine as can be tried; but, it is far from being generally efficacious. It is highly deserving of recommendation for irritable scrophulous ulcers. There is now not the least doubt, however, that the statements of Baron Stork are greatly exaggerated. He considered cicuta indicated, whenever obstructions and tumours existed; and, under this treatment, he says that he found the swellings melt away, like ice. What is extraordinary, every sort of tumour yielded to cicuta. But, (as Dr. Thomson judiciously remarks) universal success is always one of the most suspicious circumstances, which can be mentioned in the history of the effects produced by any new remedy. (*Lectures, &c. p. 199.*) Dr. Cullen frequently employed hemlock, and sometimes found it useful in discussing obstinate swellings; but, he says, it also frequently disappointed him, and he never saw it dispose scrophulous ulcers to heal.

With regard to mercury, we have already noticed, that calomel was much employed by Mr. White. Some have exhibited the sublimate; others the acetite of mercury. All these preparations have been at times conjoined with cicuta, antimony, &c. Calomel is, perhaps, the best mercurial preparation in scrophulous cases; but, mercury, given internally with any view of exciting a salivation, is justly deemed hurtful by all the best practitioners. As an alterative, and an occasional purgative, it is undoubtedly a good medicine for strumous patients. Mercury was much disapproved of by the celebrated Cullen, as a medicine for scrophula. As a distinguished Professor observes: "From the great apparent similarity of the symptoms, progress, and seats of scrophula, to those of syphilis, and from the well known effects of mercury in curing syphilis, it need not seem strange, that medical men should have been a little obstinate in their attempts to obtain benefit from the use of mercury in scrophula. These expectations are in general abandoned, and mercury is now given for the cure of scrophula as a purgative only. A long continued, or improperly administered course of this medicine, has often been known to aggravate all the symptoms of scrophula; and, in many instances, to excite these symptoms in persons, in whom they did not previously exist." (See *Thomson's Lectures on Inflammation, p. 194—195.*)

Mr. Burns thinks the nitrous acid has some effect in promoting the suppuration of scrophulous glands, and tumours, and

disposing ulcers to heal. He says, two, or three drams may be given every day, for a fortnight; but, if in this time, it should do no good, its employment ought to be discontinued. The mineral acids, diluted with water, (says Professor Thomson), are often used with views similar to those, which guide us in the employment of tonic remedies. Their medicinal powers appear to be nearly the same; but, the nitric acid has of late been preferred, particularly in the scrophulous affections, which are sometimes induced by the action of mercury. (*Lectures, &c. p. 197.*)

The pills containing carbonate of soda, (see *Pilula*,) and the different soda waters, sold at the shops, have repute, for their good effects on scrophulous constitutions, and diseases. A spirituous infusion of gentian, into six ounces of which are put thirty-six grains of the carbonate of soda, or the same quantity of the carbonate of ammonia, is a medicine highly spoken of by Richerand for scrophulous cases. (*Nosographie Chir. Tom. 1, p. 184, Edit. 4.*)

Eight, or ten drops of the hepatized ammonia, given thrice a day, are useful, according to Mr. Burns, in irritable strumous ulcers. The breathing of oxygen gas has been proposed; but, of this plan I can say nothing myself.

The sentiments of Dr. Cullen are decidedly against antimony. As a modern writer observes, no great dependence seems ever to have been placed in the use of diaphoretic medicines for the cure of scrophula. The different preparations of antimony, indeed, have been occasionally administered; but, chiefly in cutaneous affections, supposed to be of a scrophulous nature. Guaiacum, sarsaparilla, sassafras, and mezereon, singly, and in combination, have all been supposed to be useful in the cure of scrophula; but they are now seldom given with this view, except in cases of scrophula combined with syphilis, or excited by the too free and injudicious use of mercury. (*Thomson's Lectures, &c. p. 199.*)

The local treatment, preferred by Mr. White, has been already described. I have only a few words to add, concerning this part of the subject. Dr. Cullen states, that, in his practice, he had very little success in discussing incipient scrophulous tumours by topical applications; and that a solution of the saccharum saturni, though sometimes useful, more frequently failed. Dr. Cullen found the aqua ammoniæ acet. not more successful. "Fomentations of every kind (says he) have been frequently found to do harm; and poultices seem only to hurry on a suppuration. I am doubtful, if this last be ever practised with advantage; for scrophulous tumours sometimes spontaneously disappear, but never after any degree of

inflammation has come upon them ; and, therefore, poultices, which commonly induce inflammation, prevent that discussion of tumours, which might otherwise have happened." Even when scrophulous tumours have advanced towards suppuration, Dr. Cullen thought, that hastening the spontaneous opening, or making one with a lancet, was hurtful.

With respect to ulcers, Dr. Cullen remarks, that escharotic preparations, of either mercury, or copper, have been sometimes useful in bringing on a proper suppuration, and thereby disposing the ulcers to heal ; but, they have seldom succeeded, and more commonly, they have caused the ulcer to spread more. The escharotic, from which Cullen saw most benefit result, is burnt alum, mixed with some mild ointment. But, this celebrated writer gives the preference to keeping the sores continually covered with linen wet with cold water in the day-time, and some ointment, or plaster at night. Cullen says, that he usually found sea-water too irritating, and no mineral water better, than common water. (*First Lines of the Pract. of Physic, Vol. 4.*)

Formerly the extirpation of scrophulous tumours was advised ; but, this method is now considered as being, for the most part, injudicious, and unnecessary, with the exception of diseased joints, and a few other parts, which frequently require being amputated, for the sake of saving the patient's life. Certainly, no particular danger (generally speaking) would attend cutting out scrophulous glands, and tumours ; the objections to the plan are founded on the pain of the operation ; on the number of such glands frequently diseased ; on their often subsiding, either spontaneously, or by surgical treatment ; on the operation doing no good to the general affection of the system, &c. When, however, a scrophulous testicle, breast, or joint, seriously impairs the health, and endangers life, the very existence of the patient demands the immediate removal of the diseased part. Wiseman relates, that he was in the habit of cutting out scrophulous glands, and tumours, with great success ; but, for reasons, already alleged, most of the moderns think such operations in general at least unnecessary.

Caustics have been employed for the same purpose, instead of the knife ; but, as they effect the object in view less certainly, more painfully and tediously, and cause extensive ulcers, they are disused by all the best surgeons of the present day.

Some authors have advised making issues, and keeping them open, in order to prevent any ill effects from healing scrophulous ulcers. Issues are certainly quite unnecessary for any purpose of this

kind ; but they are eminently useful as a part of the local treatment of scrophulous joints and abscesses, as we have more particularly explained in the articles *Joints, Lumbar Abscess, and Vertebrae*.

Mr. Burns notices, that issues have hitherto been chiefly used in diseases of the bones and joints ; but, he adds, that it is reasonable to suppose, that they ought likewise to be useful in the cure of enlargements of the glands, and other scrophulous tumours, if inserted in the immediate vicinity of the part. The only objection to their use is the scar, which they leave, and which, in certain situations, one would particularly wish to avoid. When the tumour is thickly covered with the integuments, the issue may be made directly over it, and kept open with the savine ointment. In other cases, a small pea issue, or seton, may be inserted by the side of the tumour. This method would be objectionable, for scrophulous glands in the neck, in consequence of the scar ; but, it might be employed, when the mamma is diseased. (*Dissertations on Inflammation, Vol. 2.*)

Preparations of lead ; cloths dipped in cold water, sea-water, or weak vegetable acids ; æther ; sea-salt mixed with bile ; the linimentum camphoræ ; a mixture of æther and the linimentum opiatum ; and hemlock poultices ; form a long list of applications, which have been employed for scrophulous tumours.

According to Mr. Burns, moderate pressure, by means of adhesive plaster, conjoined with the application of cold water, is one of the best plans of treating mild scrophulous ulcers, when their situation admits of it. In other cases, he recommends applying a powder, five parts of which consist of cerussa acetata, and the sixth of burnt alum. A piece of dry lint is next to be applied, and a compress, with such pressure as can be used. Benefit occasionally results from dipping the compress in cold water.

The ceratum à lapid. calamin. is a good common dressing, when it is wished not to interfere much with the progress of the ulcer. The ung. hydrarg. nitrat. rub. and the ung. hydrarg. nitrat. are the best stimulating ointments. Poultices of bread and sea-water ; solutions of alum, cuprum vitriolatum, and the hydrarg. mur. ; solutions of the nitrates of copper, bismuth, and silver ; the recent leaves of the wood-sorrel bruised ; lint dipped in lemon juice, or vinegar and water ; are among the applications to common scrophulous ulcers.

For irritable sores, diluted, hepatized ammonia ; ointments containing opium ; carrot and hemlock poultices ; a solution of opium ; and carbonic acid gas ; are commonly recommended.

The following are Mr. Russell's sentiments respecting the treatment of scrophulous ulcers: "Scrophulous complaints in general do not agree well with stimulant applications. In the treatment of scrophulous ulcers, under the ordinary circumstances of complaint, the simplest and mildest dressings answer best. When the patients are using a course of sea-bathing, it is usual to wash the sores with sea-water, over and above the momentary application of the sea-water during the immersion of the whole body. Cold spring water is likewise a favourite application with many practitioners; and, from much observation, it appears that the operation of cold is well suited to counteract the state of inflammation, which accompanies scrophulous sores. Preparations of lead are, upon the whole, very convenient and useful applications, provided the solutions be used in a state of sufficient dilution to prevent irritation. Liquid applications are applied by means of wet linen, which is renewed whenever it dries, so that the surface of the sore may be kept constantly moist, when under this course of management. Upon the same principle, simple ointment and Goulard's cerate, furnish the best dressing in ordinary cases.

"Scrophulous congestions, of a solid nature, in the more external parts of the body, are little adapted to the practice of local bleeding, unless they be attended with symptoms of inflammation; but as some degree of inflammation is, in general, present during the incipient stage, it may be prudent to employ local bleeding in moderation at the commencement of the attack, although there may be no indication to persist in the practice, after the complaint has advanced farther in its progress. If, however, these congestions are more of an indolent nature, unaccompanied with heat or pain, there is no benefit to be expected from the local detraction of blood; warm fomentations, together with the use of stimulants, and a repetition of blisters, are the most serviceable class of remedies: such cases, too, are the best adapted to the use of friction as a discutient. Friction, indeed, has long been employed for this purpose; but, of late years, it has been introduced to an extent, and with an effect, far beyond the experience of all former practice. As yet, it has been circumscribed to the practice of a very few individuals, with whom it is said to have performed very great cures; and if, upon the test of more extensive experience, it is found to answer its present high character, I shall consider the use of repeated frictions to be one of the most valuable improvements which has been introduced into practice in modern times. The safety and simplicity of the practice recommend it very strongly to favour,

though I am afraid they are the very circumstances which retard its adoption by the public in general. I only regret that I do not feel myself entitled to give a decided opinion upon the subject from my own experience, though I have known some instances of successful cures; but the reports of success are so numerous and so well supported, that I am inclined to think very favourably of the practice.

"There is no substance interposed between the surface of the swelling and the hand of the person who administers the friction, excepting a little flour, to prevent the abrasion of the skin. The friction is applied regularly two or three hours every day, with great celerity, the hand being made to move to and fro one hundred and twenty times in a minute, and the course may require to be continued without interruption, for some months." (See *Russell on Scrophula*.)

I shall not enlarge upon this endless subject, which still stands in need of elucidation, as much as any disease, that can be instanced. The scrophulous affections of the joints are explained in *Joints*. *Bronchocele*; *Lumbar Abscess*; *Spina bifida*; and *Vertebrae*, are other articles, containing matter connected with the preceding observations.

SCROTOCE'LE. (from *scrotum*, and *κελη*, a tumour.) A rupture, or hernia in the scrotum.

SCROTUM, CANCER OF, (*Chimney-sweeper's Cancer*. *The soot-wart*.) Mr. Pott gives the following account of this peculiar disorder.

"It is a disease, which always makes its first attack on, and its first appearance in the inferior part of the scrotum; where it produces a superficial, painful, ragged, ill-looking sore, with hard and rising edges: the trade call it the soot-wart. I never saw it under the age of puberty, which is, I suppose, one reason why it is generally taken, both by patient and surgeon, for venereal, and being treated with mercurials, is thereby soon and much exasperated: in no great length of time, it pervades the skin, dartos, and membranes of the scrotum, and seizes the testicle, which it enlarges, hardens, and renders truly and thoroughly distempered; from whence it makes its way up the spermatic process into the abdomen, most frequently indurating and spoiling the inguinal glands: when arrived within the abdomen, it affects some of the viscera, and then very soon becomes painfully destructive.

"The fate of these people seems singularly hard: in their early infancy, they are most frequently treated with great brutality, and almost starved with cold and hunger; they are thrust up narrow, and sometimes hot chimneys, where they are bruised, burned, and almost suffocated; and when they get to puberty, become peculiarly liable to a most noisome, painful, and fatal disease.

"Of this last circumstance there is not the least doubt, though perhaps it may not have been sufficiently attended to, to make it generally known. Other people have cancers of the same parts; and so have others beside lead-workers, the Poitou colic, and the consequent paralysis: but it is nevertheless a disease to which they are peculiarly liable; and so are chimney-sweepers to the cancer of the scrotum and testicles.

"If there be any chance of putting a stop to, or preventing this mischief, it must be by the immediate removal of the part affected; I mean that part of the scrotum where the sore is; for, if it be suffered to remain until the virus has seized the testicle, it is generally too late even for castration. I have many times made the experiment; but though the sores, after such operation, have, in some instances, healed kindly, and the patients have gone from the hospital seemingly well, yet, in the space of a few months, it has generally happened, that they have returned either with the same disease in the other testicle, or in the glands of the groin, or with such wan complexions, such pale leaden countenances, such a total loss of strength, and such frequent and acute internal pains, as have sufficiently proved a diseased state of some of the viscera, and which have soon been followed by a painful death.

"If extirpation ever bids fair for the cure of a cancer, it seems to be in this case; but then the operation should be immediate, and before the habit is tainted. The disease, in these people, seems to derive its origin from a lodgment of soot in the rugæ of the scrotum, and at first not to be a disease of the habit. In other cases of a cancerous nature, in which the habit is too frequently concerned, we have not often so fair a prospect of success by the removal of the distempered part; and are obliged to be content with means, which I wish I could say were truly palliative: but here the subjects are young, in general in good health, at least at first; the disease brought on them by their occupation, and in all probability local; which last circumstance may, I think, be fairly presumed from its always seizing the same part: all this makes it (at first) a very different case from a cancer, which appears in an elderly man, whose fluids are become acrimonious from time, as well as other causes; or from the same kind of complaint in women who have ceased to menstruate. But be all this as it may, the scrotum is no vital organ, nor can the loss of a part of it ever be attended with any, the smallest degree of inconvenience; and if a life can be preserved by the removal of all that portion that is distempered, it will be a very good and easy composition; for when the disease has got head, it is rapid in its progress, painful in all its attacks, and most certainly destructive in its event." (*Pott's Works, Vol. 3.*)

SCROTUM, *Sarcomatous Thickening and Enlargement of*. It is the particular opinion of M. Larrey, that this is the case, which properly merits the appellation of sarcocele. He notices that Fabricius ab Aquapendente, Hildanus, André Delacroix, Lanfranc, and Fallopius, all described the sarcocele under the name of "*caro adnata ad testem*;" but that since the time of these authors, who appear to have observed the sarcocele in warm climates, the moderns have usually applied the term to several diseases of the testicle itself. (*See Testicle.*)

The investigations of the same gentleman lead him to believe, that cases of enormous growth of the scrotum are endemial in warm countries, or, at least, that they are seldom observed in cold climates; since most of the examples, which have been seen in Europe, came from Asia and Africa. The scrotal tumour of M. Delacroix, formerly minister of external relations, says M. Larrey, is perhaps the only well authenticated instance of the origin of such a disease in our own climate; and it was also much smaller, than the instances related in the *Ephemerides German.* for the year 1692, in the surgical writings of Dionis, in the 9th vol. of the *Bibliothèque de Médecine*, and those which

M. Larrey was surprised to meet with in Egypt. The smallest of these latter, after they had attained their full size, weighed more than 25 kilograms (between 60 and 70 pounds.)

Several cases of this curious disease are recorded by other writers, particularly by Dr. Cheston, Dr. Titley, and the celebrated Sandifort. I lately saw in Mr. Abernethy's museum, a considerable fleshy substance, which was a portion of diseased scrotum.

In the cases, which M. Larrey had an opportunity of seeing in Egypt, the fleshy mass, into which the scrotum was converted, was broad below, and suspended from the pubes by a sort of pedicle. "Externally (as M. Larrey observes), the tumour presents rugosities of different sizes, separated by particular lines, or sinuses, to which the mucous cryptæ and roots of the hairs correspond. Upon a large portion of its surface, especially when the case is of long standing, yellowish scaly crusts are always seen, the detachment of which constantly leaves so many small herpetic ulcers, which emit an ichorous discharge. The tumour is indolent, and hard at some points, but softish at others. It may be handled, and pressed in different directions, without the least pain. The patient is only incommoded by its weight, and the impediment which it causes to his walking well. Hence, he is necessitated to employ a suspensory bandage. In consequence of the situation of the urethra, the urine dribbles over the swelling; but without causing any excoriation." In most of the cases, seen by M. Larrey, the spermatic chord and testicles were in the natural state, situated at the sides and at the root of the swelling. The spermatic vessels, however, are somewhat enlarged and elongated. All the patients were likewise more or less affected with elephantiasis.

M. Larrey attempts to explain the causes of the complaint in Egypt, but, as I think, without any degree of success. As the affection is seldom seen in cold countries, climate has certainly a chief effect. Employments which keep persons a good deal in a sitting posture; the loose breeches worn by the Egyptians, and the consequently pendulous state of the scrotum; diseases of the humours, and particularly itchy pustules, on the part, an ordinary consequence of syphilis in that country; bad regimen; abuse of venery; and the immoderate use of the warm bath; are merely conjectures, which will not bear the test of reasoning.

The enormous magnitude, which this sort of disease may attain, is almost incredible. The case, recorded in the *Ephemerides Germanæ*, weighed about a hundred kilograms, or more than two hundred weight. Another, described by M. Larrey, was calculated to weigh about one hundred and twenty pounds, and this surgeon likewise

saw in Egypt ten, or twelve more instances, nearly as large, and all of the same character.

A very curious example, in which a similar disease affected the labia pudendi in a surprising degree, is also detailed by M. Larrey. The woman was a native of Cairo.

In the early stage of the disorder, we may try preparations of antimony combined with sudorifics; drinks acidulated with sulphuric acid, lotions containing the same acid, or the oxymuriate of mercury, the oxyde of copper, or the muriate of ammonia. These means are to be assisted by a gradual, uniform compression of the whole tumour. In one case, incisions and the application of caustic, proved of no service, and M. Larrey very properly condemns such experiments.

When the disease resists every plan tried for its relief, and its increase renders the patient's life irksome, and wretched, the extirpation of the tumour with a knife becomes proper. In this proceeding, the chief skill consists in doing no injury to the spermatic chords and testicles, which are generally perfectly sound. As the substance of the swelling is not furnished with large vessels, the hemorrhage need not be feared. Care must also be taken not to injure the corpora cavernosa penis, and the urethra. After the operation, the skin is to be brought over the exposed testicles, as much as possible, with adhesive plaster and a bandage.

M. Delonnes successfully removed the diseased mass in the celebrated case of the French minister Delacroix, and M. Larrey performed the same operation with success, when he was in Egypt. Dr. Titley, of the island of St. Christopher, also cut away such a tumour, which weighed seventy pounds, and the patient, who was a negro, and also affected with elephantiasis, speedily recovered. (See *Medico-Chirurgical Trans.* Vol. 6, p. 73, &c.)

It is probable, that some of the cases, which occur in warm countries, are analogous to the elephantiasis; but I do not believe, that the scaly incrustations, which are represented by M. Larrey as occurring in the cases, which he saw in Egypt, have been always noticed in the instances, which have taken place in colder countries. Nor, indeed, did they take place in the instance recorded by Dr. Titley, the surface of the tumour having been quite smooth. See *Larrey's Mémoires de Chirurgie Militaire*, Tom. 2, p. 110, et seq. *Richerand's Nosographie Chir.* Tom. 4, p. 314, &c. Edit. 4. Also *Delonnes' Memoir*. Dr. Cheston's Case, &c. *Med. Chir. Trans.* Vol. 6.

SEARCHING. The operation of introducing a metallic instrument, through the urethra into the bladder, for the purpose of ascertaining whether the patient has a stone or not. See *Sounding*.

SETON. (*Setaceum*, from *seta*, a bristle, because horse-hairs were formerly used for keeping open the wound.) A kind of issue. It is usually made by means of a particular needle, which is of various breadths, from half an inch to a full inch. The needle is commonly a little curved, but, if straight, it would be better calculated for the purpose. From the point, to its broadest part, it is double-edged, and, behind, it has a transverse eye, through which a skein of thread, or silk, of exactly the same breadth as the needle, is placed.

A fold of skin is to be pinched up, at the part where the seton is designed to be made, and the needle is to be pushed through it, together with the skein of thread, which is to be dipped in sweet oil. The instrument is not to be introduced too low into the base of the fold, nor too high, near its edge. In the first case, the muscles, and parts, which ought to be avoided, might be wounded; in the second, the interspace between the two wounds would be very narrow, and the seton soon make its way through it.

When no seton-needle is at hand, the fold of the skin may be punctured with a lancet, and the skein of thread introduced by means of an eye-probe. A seton may be applied almost to any part of the surface of the body, when circumstances require it; but, one of its openings should always be made lower, than the other, that the matter may readily flow out. The skein of thread is to remain untouched, for a few days after the operation, until the suppuration loosens it. Afterwards the part of the thread, nearest the wound, is to be smeared with oil, white cerate, or any digestive ointment, and drawn under the fleshy interspace between the two wounds, and what was there before is to be cut off. The seton is to be drawn in this manner once, or twice, a day, according as the quantity of matter may require. A new skein of silk, or thread, is to be attached to the preceding one, as often as necessary. Care is to be taken to keep the thread on the outside of the wound well covered, and free from the discharge, which would make it stiff and hard, and apt to occasion pain and bleeding on being drawn into the wound. If the discharge should be deficient in quantity, powdered cantharides may be mixed with the digestive ointment.

SHINGLES. See *Herpes*.

SIGHT, DEFECTS OF. There are persons, who, from their infancy, are incapable of distinguishing one colour from another. A man, who was affected with this infirmity, could not distinguish green at all. Green and red appeared to him the same. Yellow and blue he could discern very well. With regard to dark-red and dark-blue, he frequently made mistakes. In other respects, his vision was

sound and acute. The father of this patient was afflicted with the same infirmity. The mother and one sister were free from it. Another sister and two of her children had it. The patient himself had two children, who did not labour under the disorder. (See *Phil. Trans. Vol. 68, Part 2.*) Another subject, whose eyes were in other respects healthy, and whose eyesight was sharp, could not distinguish a dark-green from a dark-red.

An interesting example of this curious imperfection of vision has lately been published by Dr. Nicholl, of Cowbridge. (See *Medico-Chirurgical Trans. Vol. 7, p. 477, &c.*) The subject was a healthy boy, eleven years of age, whose eyes were grey, with a yellow tinge surrounding the pupil. He never called any colour green. Dark bottled green he called brown. He could distinguish light yellow; but darker yellows and light browns, he confounded with red. Dark brown he mistook for black. Pale green he called light red; common green he termed red. Light red and pink he called light blue. Red he called by its proper name. He could distinguish blue, both dark and light. On the mother's side, the boy had some relations, whose sight was similarly affected.

Sometimes, objects appear to the eye to be of a different colour from what they really are, not because there is any thing wrong in the eye itself, but in consequence of the unclear and coloured light by which the object is illuminated. Thus, for instance, a bad tallow candle, which emits a yellow flame, makes every thing appear yellow. When brandy is burning, all objects appear blue. In short, it is only by the light of the sun, that any object can be seen in its clear natural hue. In certain cases, the infirmity is owing to the transparent parts and humours of the eye, which do not happen to be of a proper colour. Thus, persons having the jaundice in a high degree, see all things yellow, because the transparent parts of the eye are of that colour. When, in consequence of external violence applied to the eye, blood is effused, and the aqueous humour rendered red by this fluid, all objects seem to the patient to be red; and, white, when the aqueous humour has been made of this colour by the couching of a milky cataract. Sometimes this defect in vision is ascribable to the duration of an impression. When one has surveyed a bright coloured object a long while, as for example a bright red or yellow wall, on which the sun shines, that colour will often remain a good while before the eyes, although one may not be looking any more at an object of this hue. There are some eyes, which seem much disposed to retain the impression of objects, which are not very bright coloured; but, such a disposition always betrays great weakness and irritability of those

organs. The most frequent cause of this defect in vision, is an irritation operating upon the optic nerves, so as to produce the irritability in them, which alone makes objects appear of one colour. The seat of such irritation, according to Richter, is also most commonly in the abdominal viscera, and the case demands evacuations, tonics, and anodyne medicines. But, the disorder may also originate from other causes. The operation of bright-coloured or shining objects upon the eye, sometimes has for a certain time afterwards, the effect of making objects of diverse colours appear to be moving before the eyes. In extreme terror, or fright, things may also seem to have a different colour from their real one. The same often happens in fevers attended with delirium. A sudden exposure of the head to cold, at a period, when it was perspiring much, in one instance, caused many coloured appearances before the eyes; but, the disorder subsided in a couple of days. (*Richter's Anfangsgr. der Wundarzneykunst, Band. 3, p. 523.*)

Also a healthy eye sees a distant object with uncertainty, and error, in a room, or space, the extent, length, and breadth, of which are unknown, when the size of the object itself is unascertained, and when there are few or no other objects intervening at a smaller distance between the eye and the thing looked at. The more numerous the objects are between the eye and the principal thing looked at, the more distant it is made to appear; the fewer they are, the nearer it seems to be. In a country covered with snow, and upon the sea, very distant objects appear to be close. The smaller an object is to the eye, in relation to its known magnitude, the further off it seems. The errors, which the eye makes, in regard to the distance of objects, also tend to deceive. But, there are certain cases, in which the eye is almost entirely incapable of judging of the distance of objects. The first is, when the object, of which we wish to ascertain the distance, is looked at with only one eye. Hence all one-eyed persons, and persons affected with strabismus, are unable to judge well of the real distance of objects. However they are only so for a certain time; and, by practice, they gradually acquire the faculty. Even when two eyes are employed, it requires some exercise, in order to enable them to judge of the right distance of objects. Persons, born blind, but who have their sight restored in both eyes by the operation for the cataract, are a long while incapable of judging of distances, and only obtain this power very gradually. Lastly, this infirmity is sometimes owing to an irritation affecting the optic nerves, whereby their sensibility is so altered, that distant objects make the impression upon them of near ones. In this circum-

stance, all objects appear to the patient closer than they really are. This is the only case, which admits of being treated as a disease. The irritation, producing the disorder, is mostly seated in the abdominal viscera, and requires evacuations and such medicines as invigorate the nerves. A suppression of the perspiration is alleged to be sometimes a cause. (*Richter's Anfangsgr. der Wundarzn. Band. 3, p. 525.*)

A sound eye likewise does not always judge with accuracy and uniformity of the magnitude of objects. This may arise from three causes. In order to judge rightly of the size of any thing, its precise distance must be known; for, the more remote it is, the smaller will it seem to the eye. Hence, any conjecture, respecting the magnitude of an object, is constantly erroneous, unless the distance be ascertained. Size is invariably something relative. A single large object, surrounded by many small ones, always appears to be larger, than it really is; et vice versa. An object, whose magnitude is known, seems smaller, than it actually is, when one has been a little previously looking at another that is still larger. Lastly, the refraction of the rays of light in the eye, by which operation an object is made to appear large or small, is not always accomplished in the same degree, as the eye is not at all times equally full and distended with its humours. Hence, at one time, the same object will appear to the same eye, and at the same distance, larger; at another time, smaller. Sometimes, however, the eye judges so erroneously of the magnitude of objects, that there is reason for regarding the case as an infirmity, or disease. It is for the most part owing to a defective sensibility in the nerves, caused by some species of irritation acting upon the eye, and generally seated in the gastric organs. A man, to whom every thing seemed one half smaller and nearer, than it really was, was cured by means of an emetic, bark, an issue and valerian. (*Leutin, obs. fascic.*)

Sometimes to the eye, under circumstances of disease, straight lines appear serpentine; perpendicular objects, sloping, things standing upright, to be inverted, &c. All these cases are set down by Richter as depending upon a wrong sensibility of the nerves, occasioned by the effect of some irritation. The irritation, he says, may be of many kinds; but, experience proves, that it is mostly seated in the gastric organs. These defects of sight may generally be cured by first exhibiting emetics and purgatives, and afterwards having recourse to remedies for strengthening the nerves, bark, oleum animale, valerian, issues, &c. One mark of a very weak and irritable eye, is when objects, after being looked at a good while, and pre-

senting a right appearance, begin to move, swim about, mix together, and, at length, become quite indistinguishable. This principally happens when the objects regarded are small and strongly illuminated. Here such remedies, both general, and topical, as have the effect of invigorating the nerves, are indicated. However, sometimes, the infirmity is partly owing to the operation of some species of irritation, which will require removal, ere the tonic medicines and applications can avail. Indeed, in particular cases, the dispersion of such irritation is alone sufficient to accomplish the cure.

Sometimes, all objects appear to the eye, as if they were in a more or less dense mist. This defect in vision is always owing either to some slight opacity of one of the humours of the eye, or to excessive debility of the optic nerves. (See *Richter's Anfangsgr. der Wundarzn. Band. 3, p. 521, &c.*)

SINUS.—A long, narrow, hollow track, leading from some abscess, diseased bone, &c.

SOLUTIO ARGENTI NITRATI.—*R. Argenti Nitrati ℥j. Aq. Distillat. ℥ss. M.* This is a very good application for sores, which are frequently met with round the roots of the nails, both of the fingers and toes. It is also useful in herpetic affections, noli-me-tangere, and several kinds of ulcers. The proportion of the argentum nitratum may be lessened, or increased, as occasion requires. A strong solution of this substance is a good application for destroying warts, to which it must be applied by means of a hair-pencil. When used for sores, it is best to dip little bits of soft lint in it, lay them on the part affected, and cover them with a common pledget.

SOLUTIO FERRI SULPHATIS.—*R. Ferri Sulphatis ad albidinem calcinati ℥j. Aq. Distillat. ℥viij. Misc.* Has been recommended as an application for sores on the nipple, and other ulcers.

SOLUTIO HYDRARGYRI CUM PLUMBO.—*R. Hydrarg. ℥ij. Plumbi ℥iss. Acidi Nitrosi ℥j.* The two metals are to be dissolved in the acid, in a glass vessel, placed in a sand heat. Plenck employs this caustic solution for destroying warts, and excrescences.

SOUND. An instrument, which surgeons introduce through the urethra into the bladder, in order to discover, whether there is a stone in this viscus, or not. The sound is usually made of very highly polished steel, that it may be well calculated for conveying to the surgeon's fingers the sensation of any thing, against which its end may strike. It is also generally rather less curved, than a catheter, so that its extremity may be more easily inclined to the lower part of the bladder, where the stone is most frequently situated.

SOUNDING. The operation of introducing the foregoing instrument.

Sounds are generally introduced much in the same way as catheters, either with the concavity towards the abdomen, or the convexity, in which last method, it is necessary, as soon as the beak of the sound has arrived in the perineum, to bring the handle of the instrument downward by a semicircular movement to the right, while the other end is kept as much fixed as possible. This is what the French term the coup, or tour de maître; a plan, that is often followed at the present day, though, except in very corpulent subjects, it has no particular recommendation.

When a patient is to be sounded, he is usually put into a posture very similar to that adopted in the lateral operation for the stone, with the exception that he is not bound in this position, as there is sometimes an advantage in making the patient stand up, in order that the stone may come into contact with the end of the sound. The instrument having been introduced, its extremity is to be turned, and moved in every direction, when, if there be a calculus, its presence will usually be indicated by the collision against the beak of the sound.

Stones have sometimes been found in the bladder after death, although they could never be discovered with a sound while the patient was alive, suffering all the symptoms of the complaint. The celebrated French surgeon La Peyronie was thus circumstanced: he was so fully convinced of there being a stone in his bladder, notwithstanding neither he, nor any of his friends could feel it with a sound, that, on his death-bed, he gave directions for ascertaining the fact. Hence, when the usual symptoms of a stone in the bladder continue, patients should be searched several times, before a positive opinion is delivered respecting the nature of the disease. When during the operation of sounding, all the urine has escaped from the bladder, the inner surface of this viscus comes into contact with the end of the sound, and such a sensation may be communicated to the surgeon's fingers as leads him to suspect that a fungus, or some other hardish extraneous substance, is contained in the bladder. In such cases, patients have actually been cut for the stone, when no foreign body whatever was present. (See *Sabatier's Médecine Opératoire, Tom. 3. p. 127—128. Edit. 2, and p. 680 of this Dictionary.*)

SPE'CULUM. An instrument intended for facilitating the examination of parts, and also the performance of operations on them: thus we have specula ani, specula oculi, auris, &c.

SPHA'CELUS. (from σφαζω, to destroy.) Surgeons imply, by this word,

complete mortification, which is mostly preceded by a stage of the disorder, termed *gangrene*. See *Mortification*.

SPICA. (from *σπῆχυς*, an ear of corn.) A name, given to a kind of bandage, in consequence of its turns being thought to resemble the rows of an ear of corn.

In order to apply the spica bandage, employed in dislocations of the shoulder, we are to take a common single-headed roller, and place the end of it under the opposite arm-pit. After conveying the bandage backward, obliquely over the shoulders, we are then to bring it forward over the head of the dislocated bone. The roller is next to descend under the arm-pit, then be carried upward again, and made to cross on the deltoid muscle. The roller is now to be carried obliquely downward over the front of the chest, and under the opposite arm-pit, where the end of it is to be pinned, or stitched. The bandage is next to pass across the back, over the part of the roller previously applied in this situation, and is to be conveyed round the head of the os brachii, so as to form a turn, or *doloire*, with the first circle of the roller. Three, or four *doloires*, or turns, each of which covers about one-third of the preceding one, are to be made, and then the upper part of the arm is to be once surrounded with a plain circle of the bandage. This last circular application leaves between it, and the cross previously made, a triangular, equilateral, space, technically named by writers *geranis*. The roller is now to be carried upward in a spiral manner; its head is to be brought to the opposite arm-pit, and the application of the whole concludes with a few turns round the body. The bandage is to be fastened with pins at the place where it commenced.

Before putting on the spica, the injured part, and margin of the axillæ, must be guarded from the effects of the pressure by compresses.

The spica bandage for the broken clavicle is applied in the same manner, with the exception, that the crossings are made over this bone. It is proper to state in this place, that the spica is a very ineffectual bandage, for this kind of accident. (See *Fractures of the Clavicle*.)

In order to apply, what is named, the *spica inguinis*, the end of the roller is to be placed on the spine of the os ilium, of the affected side. The bandage is then to be carried obliquely over the groin, and under the perinæum. Then it is to pass over the back of the thigh, and next forward, so as to cross the part previously applied on the front of the groin. The application is continued by carrying the roller over the pubes, over the opposite os ilium, and next round the body above the buttocks. The bandage thus returns to the place, where it began. Its applica-

tion is completed by making a few *doloires*, and turns, like the preceding ones, and lastly, a few turns round the body.

The spica for the thigh is applied in the same way; only the crossings are to be made on the upper and outer part of the limb. (See *Encyclopédie Méthodique, Part. Chirurgicale, Art. Spica*.)

SPINA BIFIDA. (i. e. the Cloven Spine.) *Hydro-Rachitis*. A disease, attended with an incomplete state of some of the vertebræ, and a fluid swelling, which is most commonly situated over the lower lumbar vertebræ, sometimes over the dorsal and cervical ones, and in some instances, over the os sacrum. The same name has also been given to an analogous tumour, which sometimes occurs on children's heads, attended with an imperfect ossification of a part of the cranium.

The Arabians, who first treated of this disease, erroneously imputed the deficiency of one, or more of the spinous processes to the tumour, while it is now well known, that the incomplete state of the affected vertebræ is a congenital malformation, and that the swelling is only an effect. In fact, the tumour generally becomes larger and larger, the longer it continues. The spina bifida may be regarded as an affliction only met with in children: few, very few, live to the adult age with this incurable affection. Warner, however, has related a case, in which the patient lived till he was twenty.—(*Cases in Surgery, p. 134, Edit. 4.*)

As I have remarked, the swelling is most frequently situated towards the lower part of the spinal canal, particularly at the place, where the lumbar vertebræ join the sacrum. The fluid, which it contains, resembles serum, being somewhat more liquid, than the white-of-egg, and, like the latter, frequently coagulable. It is in general limpid and colourless; but, occasionally, it is turbid, and tinged with blood. On pressing the tumour, a fluctuation is very perceptible, and a preternatural space may also be felt existing between some of the spinous processes. The fluid is contained in a kind of cyst, which is composed of the continuation of the dura mater, investing the spinal canal, and is usually closely adherent to the integuments.

Spina bifida is sometimes attended with hydrocephalus. It has even been recorded, that the enlargement of the head has undergone a considerable diminution, when the tumour of the spine casually burst, and discharged the fluid, which it contained; a proof of some communication between the two parts. (*Ephem. Cur. Nat. Decad. 3, Ar. 1, Decad. 2, Art. 2.*) The fluid, which was lodged in the lateral ventricles, and third ventricle, passed into the fourth, through the aqueductus Sylvii, ruptured

the calamus scriptorius, and thus got into the spinal canal.

Spina bifida usually occur on the lower part of the spine; but, they occasionally take place on the cervical vertebrae, in which latter situation, the tumours have the same characteristic marks, as those which form near the sacrum. Many facts, recorded by Ruysch, in his Anatomical Observations, confirm the preceding account.

The present affliction is one of a most incurable nature; at least, (with the exception of two or three examples recently published by Mr. Astley Cooper,) there is not, I believe, in all the records of medicine, or surgery, any case, which either got well of itself, or was benefited by any mode of treatment. Opening the tumour, either with caustics, or cutting instruments, has hitherto only tended to hasten the fatal event of the disease. Death soon follows an operation of this kind, and, it is said, that the child sometimes dies immediately. Tulpius observes on this subject; *quam calamitatem si quidem reformides, chirurge, cave sis improvide aperias quod tam facile occidit hominem.* Observ. Med.

But, whether the tumour be opened, or not, still the disease is one of the most fatal, to which children are exposed. When afflicted with it, they very seldom live till three years of age: but, after lingering several months from their birth, suddenly die. It has been said, that children, with spina bifida, always have their legs in a paralytic state. This, however, is not true; for, the largest spina bifida I ever saw, was under my friend Mr. Maul, of Southampton, and was unattended with any weakness of the legs. Indeed, the child was, to all appearances, as stout, healthy, and full of play, as possible. The fatal event, however, took place after a time, as usual; and, if my memory does not fail me, Mr. Maul noticed, that a little before death, a remarkable subsidence of the swelling occurred, though it never burst externally. It is a fact, notwithstanding, that many infants, with spina bifida, have paralytic legs, and can neither retain their feces, nor urine.

If we draw our inferences from the cases, and remarks, offered by almost every writer on spina bifida, we must regard all attempts to cure the disorder, by making any kind of opening, as exceedingly perilous, if not positively fatal. It is to be observed, at the same time, that some very eminent surgical authors have not altogether abandoned the idea of devising a mode of accomplishing a cure, at least, in a few instances. Mr. B. Bell says, that if the tumour proceeded from disease of the spinal marrow, or its membranes, no means of cure will probably ever be discovered. But, if the deficiency

in the spinous processes of the vertebrae, with which the disease is always accompanied, is not an effect of the complaint, as was commonly imagined, and if the collection of fluid takes place, from the want of resistance in the dura mater, in consequence of the imperfection of the bones, Mr. B. Bell questions, whether it would not be proper to tie the base of the tumour with a ligature, not merely with a view of removing the swelling, but in order to resist the propulsion of the cyst further outward. Mr. Bell acknowledges, that the event of this practice must be considered as very dubious; but, expresses his wish to devise any plan, that would afford even the least chance of success, in a case which must terminate in an unfavourable manner. Mr. Bell mentioned his design of putting the method to a trial, on the first opportunity, and after the detachment of the swelling on the outside of the ligature, he intended to keep a soft compress on the part with a proper bandage. I do not know whether this gentleman ever put the above scheme in practice; but, suppose not. It is properly objected to by the author of the article *Spina Bifida*, in the *Encyclopédie Méthodique, Part. Chir.* because the disease is often attended with other mischief of the spinal marrow and brain, and the base of the swelling is almost always too large to admit of being tied at all, or not without hazard of dangerous consequences.

Richter has proposed the trial of two caustic issues at a little distance from the swelling; but, I am not acquainted with any facts in favour of this practice.

Mr. Abernethy first suggested trying a gentle degree of pressure on the tumour from its commencement, with a view of producing absorption of the fluid, and preventing the distention of the unsupported dura mater. Were the fluid to continue to increase, notwithstanding such pressure, Mr. Abernethy thinks, that as death would be inevitable on the tumour bursting, it might be vindicable to let out the fluid, by means of a puncture, made with a finely-cutting instrument. The wound is to be immediately afterwards closed with sticking-plaster, and, if possible, healed. Another accumulation is then to be prevented, if practicable, with bandages and topical applications. Mr. Abernethy actually made the experiment of trying a puncture in one hopeless instance, in which indeed, the swelling had previously just begun to burst. The puncture was repeated, every fourth day, for six weeks, during which time the child's health continued unaffected. The wounds were regularly healed; but the plaster having been rubbed off one of the punctures, the part ulcerated, the opening could not be healed, the discharge, from having been of an aqueous quality, be-

came purulent, and death ensued. This case was unfavourable for the trial of the method, as the integuments covering the tumour were diseased, and had no disposition to contract.

The annexed case, published by Mr. Astley Cooper, will serve to shew the benefit, which may be derived from pressure.

"James Applebee, Baldwin Street, Old Street, was born on the 19th of May, 1807, and his mother, immediately after his birth, observed a round and transparent tumour on the loins, of the size of a large walnut.

"Mr. Deering, who was her accoucheur, requested Dr. Petch to see the child with him, who informed the mother of the dangerous nature of the complaint, and of the probability of its fatal termination,

"On the 22d of June, 1807, the child was brought to my house, and I found, that although it had spina bifida, the head was not unusually large; that the motions of its legs were perfect; and its stools and urine were discharged naturally.

"I applied a roller around the child's waist, so as to compress the tumour, being induced to do so from considering it as a species of hernia, and that the deficiency of the spine might be compensated for by external pressure.

"The pressure, made by the roller, had no unpleasant influence on its voluntary powers; its stools and urine continued to be properly discharged, but the mother thought, that the child was occasionally convulsed.

"At the end of a week, a piece of plaster of Paris, somewhat hollowed, and that hollow partly filled with a piece of lint, was placed upon the surface of the tumour: a strap of adhesive plaster was applied to prevent its changing its situation, and a roller was carried around the waist, to bind the plaster of Paris firmly upon the back, and to compress the tumour as much as the child could bear.

"This treatment was continued until the month of October, during which time, the tumour was examined about three times a week, and the mother reported, that the child was occasionally convulsed.

"When the child was five months old, a truss was applied, similar in form to that, which I sometimes use for umbilical hernia in children, and this has been continued ever since.

"At the age of fifteen months, it began to make use of its limbs; it could crawl along a passage, and up two pair of stairs.

"At eighteen months, by some accident, the truss slipped from the tumour, which had become of the size of a small orange, and the mother observed, when it was reduced, that the child appeared in some degree dull; and this was always the case, if the truss was left off for a few minutes, and then re-applied.

"At fifteen months, he began to talk; and at two years of age, he could walk alone.

"He now goes to school, runs, jumps, and plays about, as other children. His powers of mind do not appear to differ from those of other children. His memory is retentive, and he learns with facility. He had the measles and small-pox in the first year, and the whooping-cough at three years. His head, previously and subsequently to the bones closing, has preserved a proper proportion to the other parts of the body.

"The tumour is kept by the truss entirely within the channel of the spine; but, when the truss is removed, it soon becomes of the size of half a small orange. It is therefore necessary, that the use of the truss should be continued. When the truss is removed, the finger can be readily pressed through the tumour into the channel of the spine." (*Medico-Chirurgical Transactions, Vol. 2, p. 323, &c.*)

The next case, also published by Mr. Astley Cooper, will prove, that spina bifida may sometimes be treated on another plan, so as to accomplish a permanent cure.

"January 21st, 1809, Mrs. Little, of No. 27, Limehouse Causeway, brought to my house her son, aged ten weeks, who was the subject of spina bifida.

"The tumour was situated on the loins; it was soft, elastic, and transparent; and its size about as large as a billiard-ball when cut in half; his legs were perfectly sensible, and his urine and feces were under the power of the will, &c.

"Having endeavoured to push the water, contained in the tumour, into the channel of the spine, and finding that if the whole was returned, the pressure would be too great upon the brain; I thought it a fair opportunity of trying what would be the effect of evacuating the swelling by means of a very fine pointed instrument, and by subsequent pressure to bring it into the state of the spina bifida in Applebee's child.

"I therefore immediately punctured the tumour with a needle, and drew off about two ounces of water.

"On the 25th of January, finding the tumour as large as before it had been punctured, I opened it again, and in the same manner, and discharged about four

ounces of fluid. The child cried when the fluid was evacuated, but not whilst it was passing off.

"On January 28th, the tumour was as large as at first, I opened it again, and discharged the fluid. A roller was applied over the tumour, and around the abdomen.

"February 1st, it was again pricked, and two ounces of fluid discharged.

"On the 4th, three ounces of fluid were discharged.

"On February 9th, the same quantity of fluid was evacuated as on the 4th; but, instead of its being perfectly clear, as at first, it was now sanious, and it had been gradually becoming so in the three former operations.

"On the 13th, the same quantity of fluid was taken away; a flannel roller was applied over the tumour and around the abdomen; a piece of pasteboard was placed upon the flannel roller over the tumour, and another roller over the pasteboard to confine it.

"On the 17th, three ounces of fluid, of a more limpid kind, were discharged; the pasteboard was again applied.

"On the 27th, the surface of the tumour inflamed; the fluid, not more than half its former quantity, was mixed with coagulable lymph, and the child, suffering considerable constitutional irritation, was ordered calomel and scammony, and the rollers were discontinued.

"February 26th, the tumour was not more than a quarter of its former size; it felt solid; the integuments were thickened, and it had all the appearance of having undergone the adhesive inflammation.

"On the 28th, it was still more reduced in size, and felt solid.

"On March 4th, it was in the same state as on the 28th of February.

"March 8th, the swelling was very much lessened; the skin over it thickened and wrinkled; a roller was again had recourse to; a card was put over the tumour; and a second roller was applied.

"March 11th, the tumour was much reduced; the skin covering it was a little ulcerated. On the 15th, it was flat, but still a little ulcerated.

"On the 27th, the effused coagulable lymph was considerably reduced in quantity, and of a very firm consistence.

"On the 2d of May, nothing more, than a loose pendulous bag of skin remained, and the child, appearing to be perfectly well, the bandage was soon left off.

"On December 18th, it was attacked with the small-pox, and went well through the disease.

"The skin now hangs flaccid from

the basis of the sacrum; its centre is drawn to the spine, to which it is united, and thus the appearance of a navel is produced in the tumour by retraction of the skin.

"The pricks of the needles are very obvious on each of the punctured parts of the tumour, forming slight indentations." (See *Medico-Chirurgical Transactions*, Vol. 2, p. 326—329.)

At the time when Mr. A. Cooper transmitted this case to the Medico-Chirurgical Society, it had been under his observation two years and a half.

The first of the preceding observations exemplifies the palliative treatment, adopted by the latter gentleman, and consisting of the application of pressure, in the manner of a truss for hernia; the second shews the radical mode of cure by puncturing the swelling from time to time with a needle, and exciting the adhesive inflammation, which, with the assistance of pressure, stops the disease altogether, that is to say, in such examples as admit of cure.

Children are sometimes born with tumours, which are analogous to spinæ bifidæ, but situated on the head. There is a deficiency of bone at some part of the skull, and through the opening a sac, composed of the dura mater, protrudes, covered only by the integuments. Mr. Earle lately met with such a swelling situated upon the occiput of a female infant. The plan of repeatedly making small punctures with a common needle, discharging the fluid, healing up the punctures, and applying pressure, was tried, and followed up for some time without the occurrence of any unpleasant symptoms. Punctures were sometimes even made with an ordinary lancet; yet, the child suffered no harm from the operation, and some hopes of a cure were indulged. At length, however, ulceration of the swelling took place, the child became indisposed, and rapidly sunk. (See *Medico-Chir. Trans.* Vol. 7, p. 427.)

SPINA VENTOSA. The Arabian writers first employed this term to express a disease, in which matter formed in the interior of a bone, and afterwards made its way outward beneath the skin,

Until the matter had escaped from within the bone, these authors describe, that the pain was incessant and intolerable; but that after the pus had made its way outward by fistulous openings, the pain underwent a considerable diminution. The matter sometimes insinuated itself, from the interior of the bone, into the cavities of the cellular substance, so as to render them soft and flabby, unattended occasionally with any change of colour in the skin. The swelling had some of the appearance of emphysema. To express this state, the Arabians added the term *ventosa* to that of *spina*, which was employed, before their time, to describe the nature of the pain attendant on the disease. See an account of this subject in the *Encyclopédie Méthodique, Part. Chir. Art. Spina Ventosa*.

The term *spina ventosa* has, since the time of the Arabian writers, been used by many to signify the disease named *white-swelling*, and the former might also mean by it a similar affection, though we should infer the contrary from their account of the matter passing from the interior of the bone to get under the integuments, a thing which I believe never yet happened in any case of white-swelling. Another, and, perhaps, a decisive argument, against the original signification of the word being the same as that of white-swelling, is, that it was not restricted to diseases of the joints and heads of the bones; but was also applied to abscesses, which commenced in the cavities of the middle portions of the long bones, on which parts, I need hardly observe, white-swellings never make their attack.

For these reasons many respectable authors have implied by the term *spina ventosa* an abscess, in the interior of a bone. See, on this subject, *Latta's System of Surgery, vol. 1, p. 165*. Cases of this latter kind, I know, are infinitely rare, compared with that common disorder, the white-swelling; and, I am also certain, from the descriptions given by some authors, that their cases of *spina ventosa* were in reality instances of necrosis. But, that abscesses do occur, and begin in the interior of the bones, more particularly of those of young persons, I have no doubt myself, both from two or three cases, which I remember having seen in St. Bartholomew's Hospital, and from some cases recorded by the most authentic writers. I cannot conceive, however, that suppuration can take place to any extent within a long bone, without being followed by necrosis, or as many writers improperly term it, *caries*.

J. L. Petit relates, that a man, with a tumour on the middle of the tibia, who had been treated by him as a venereal patient, found, a fortnight afterwards, that the pains, which had never ceased, now

began to grow more violent. The patient was feverish, his leg became red, and even painful, externally. An incision was made in the situation of the tumour with a view of letting out the matter which was suspected to be the occasion of the bad symptoms, and to have insinuated itself under the periosteum. The incision was of no service, and, two days afterwards, the trepan was applied, by which means, a large quantity of matter was let out. The medullary part of the bone seemed quite annihilated, and the cavity almost empty. Petit made three other perforations with the trepan, and cut away the intervening pieces of bone. The actual cautery was also used several times to destroy the caries, and the patient at length got well. (*Traité des Maladies des Os, de J. L. Petit*.) If any one doubt, that abscesses now and then form in the middle of the long bones, I must request him to consult Mr. Hey's *Practical Observations in Surgery, p. 22*, where he may peruse two very interesting cases illustrative of what Mr. Hey calls *Abscess in the Tibia with Caries*.

It must be confessed, however, that these were only cases of necrosis, for which affection of the bone the term *caries* is too often inaccurately used. Indeed, it would appear, from the observations of Dr. Macartney, that a very small suppuration in the medulla is accompanied with the beginning of those changes of the periosteum, which attend necrosis. (See *Necrosis, p. 762*.)

For an account of *spina ventosa*, in the sense of white-swelling, refer to *Joints*.

SPIRITUS AMMONIÆ COMPOSITUS. Besides the well known uses of this medicine internally exhibited, its vapours are an exceedingly proper application to the eye in some cases of chronic ophthalmia. Scarpa recommends a remedy of a similar nature.

SPLINTS. Long thin pieces of wood, or tin, or strong pasteboard, employed for preventing the ends of broken bones from moving so as to interrupt the process by which fractures unite. These instruments are sometimes used in other cases, for the purpose of keeping limbs from moving, particularly in some kinds of dislocations, wounds, &c.

In simple fractures of the arm, forearm, or even of the thigh, or leg, in young infants, it matters not whether the splints be made of wood, pasteboard, or tin. In this country, surgeons usually keep sets of splints made expressly for the leg. These are of different sizes, excavated and shaped to the part, and furnished below with apertures for the projecting malleoli. When the limb is laid upon its outside, the foot is also usually supported and

kept steady by the under splint extending some distance towards the toes. Very excellent splints for the legs of young children are made of strong pasteboard, accommodated in shape to the contour of the limb. Splints for the thigh, arm, and forearm, whether made of tin, or wood, should always be slightly concave on the side, which is to be applied to the broken limb. They should likewise be made as thin and light, as is consistent with the necessary degree of strength for preventing the broken bone from bending. The sets of splints, which are used for fractured legs and thighs in England, are frequently furnished with straps, which have a great many small perforations in them at stated distances, and can thus be easily fastened by means of little pegs for the purpose. Tapes are also sometimes employed; but they often get loose, and cannot be depended upon so well as leather straps. Pasteboard, as a material for splints, has one advantage; viz. when wet, it becomes soft, and admits of being accurately applied to every point of the surface of the limb: consequently, as soon as it dries and recovers its firmness again, it retains the exact shape of the part, and makes every where equal pressure on it, without incommoding the patient. Pasteboard, however, is hardly strong and durable enough for many fractures; nor will it answer when there is any discharge, or when the surgeon wishes to employ any fluid applications. But, it is generally allowed that no substance is better calculated for supporting the fractured lower jaw; for, it is perfectly strong enough for this particular case, and if wet before being applied, it forms when dry a solid covering, most accurately corresponding to the shape of the jaw.

Whatever may be the substance, of which splints are made, they ought always to be at least as long as the fractured bone; and if the situation of the limb will allow, they ought, says Boyer, to extend its whole length. "For instance, (says he) for simple fractures of the thighs of very young children, the pasteboard splints, which I employ, reach from the upper part of the thigh, to the lower part of the leg. Generally speaking, the longer splints are, the better they fix the limb, and keep the fracture steady." (*Boyer, Traité des Mal. Chir. T. 3, p. 50.*)

The number of splints must depend upon their breadth, and the thickness of the limb. For the forearm, two are sufficient; for the upper arm and thigh four are often used; and for the leg two, and sometimes three.

In cases of fractured thighs, when the straight position is preferred, the external splint should extend from the crista of the ilium to some little distance beyond the sole of the foot; while the inner one should

reach from the upper and internal part of the thigh also beyond the sole of the foot. With respect to the anterior splint, it is indifferent, whether it only reaches from the groin to the knee, or as far as the lower part of the leg.

The lateral splints, for a broken leg, ought to be sufficiently long to embrace the knee, and confine the motions of the foot and ankle. When the straight posture is adopted, a splint is frequently laid along the front of the leg, from the patella to the lower part of the tibia. None however can ever be required under the limb, as there the bedding itself more conveniently affords the necessary degree of support.

Of all the different pieces of the apparatus for the treatment of fractures, the splints are by far the most important and essential. Without them, indeed, it would be in vain to attempt to keep the extremities of the fracture from being displaced.

As splints are generally composed of hard materials, the bad effects of their pressure upon the skin must always be counteracted by placing a sufficient quantity of tow, wool, or other soft substance between them and the limb.

In order to understand, however, the principles, which should guide the surgeon in the choice and application of splints, many remarks, offered in the article *Fracture*, must be consulted.

SPONGIA PRÆPARATA. (*Prepared Sponge; Sponge-tent*) This is formed by dipping pieces of sponge in hot melted emplastrum ceræ compositum, and pressing them between two iron plates. As soon as cold, the substance thus formed, may be cut into pieces of any shape. It was formerly much used for dilating small openings, for which it was well adapted, as when the wax melted, the elasticity of the sponge made it expand and distend the opening, into which it had been put. The best modern surgeons seldom employ it.

SPONGIA USTA. (*Burnt Sponge.*)—This is often given in the form of lozenges, in cases of bronchocele, in which particular instances much efficacy is imputed to allowing the lozenges to dissolve gradually in the mouth, after putting them under the tongue. Burnt sponge is also exhibited in many scrofulous diseases. Its good effects are supposed to depend on the quantity of soda which it contains. The dose is from a scruple to a dram.

STAFF. An instrument of considerable importance in the operation of lithotomy, being in fact the director for the gorget, or knife, after the completion of the external incision. It is made of steel, and its handle is generally rough, in order that it may be more securely held. As it is intended to be introduced through the urethra, its shape ought to be principally de-

terminated by the natural course of that passage. The English generally employ a staff, the curvature of which forms the segment of a larger circle, than that described by the curvature of a staff used by French practitioners. (See *Roux, Voyage fait à Londres en 1814, ou Parallèle de la Chirurgie Anglaise, &c.* p. 319.) In other words, the French staff turns more upward, than ours, as it approaches and enters the bladder. There may be some advantage in this construction, inasmuch as it tends to make the gorget enter in the direction of the long axis of the bladder; yet, a great deal more seems to me to depend upon the position in which the staff is held, than upon its shape. Lithotomists should always employ as large a staff as can be easily introduced, because the operation will thereby be facilitated. The groove, the most important part of the staff, is of course situated upon the convexity of the curved part of the instrument, or upon that portion, which, when introduced, lies in the membranous part of the urethra, prostate gland, and the bladder. The termination of the groove, at the end of the instrument, should always be closed, so as to stop the further entrance of the gorget, and prevent the beak of the latter instrument from doing mischief. English surgeons have been justly censured by Desault, and Sabatier, for neglecting this essential caution; for, certainly, the most fatal injury has been done by the gorget slipping beyond the end of the staff. (See *Lithotomy.*) For my own part, if I am more sure of any one thing in surgery, than another, it is this, that the beak of a gorget ought never to pass out of, or beyond, the groove of the staff.

STAPHYLOMA. (from *σταφυλη*, a grape.) A disease of the eye, so named from its being thought to resemble a grape. Staphyloma is that disease of the eyeball, in which the cornea loses its natural transparency, rises above the level of the eye, and successively even projects beyond the eyelids, in the form of an elongated, whitish, or pearl-coloured tumour, which is sometimes smooth, sometimes uneven, and is attended with total loss of sight.

Scarpa observes, that infants are often attacked by this disease soon after their birth, and mostly in consequence of the purulent ophthalmia. It is also produced by the small-pox, yet never during its eruption, which is singular; nor during the stage of suppuration; but, when the pustules dry, and even after the detachment of the variolous scabs.

In a great number of subjects, says Scarpa, when the staphyloma has attained a certain elevation above the cornea, it becomes stationary, or only increases in due proportion to the rest of the eye. In

other instances, the small tumour of the cornea successively enlarges in all its dimensions, and in such a disproportion to the rest of the eye, that it at length protrudes considerably between the eyelids, to the great molestation and deformity of the patient.

This disease is justly considered as one of the most serious, to which the eyeball is subject; for, to the total and irremediable loss of sight that it occasions, are added all the evils which necessarily result from the bulk and protuberance of the staphyloma, after the swelling of the cornea has acquired such a size, that it can no longer be covered by the eyelids. In such circumstances, the continual exposure of the eyeball to the contact of the air, and particles of matter suspended in it; the friction of the eyelashes against it; the incessant flux of tears down the subjacent cheek; are enough to render the eye painful and inflamed; the sound one is affected by sympathy, and the diseased one at length ulcerates, together with the lower eyelid and cheek, on which it presses.

Scarpa next remarks, that surgeons have long thought, that, in this disease, the cornea yields to the distention produced by the turgescence of the humours of the eye, nearly in the same manner as the peritoneum yields to the pressure of the abdominal viscera, when an intestinal hernia takes place. Richter (*Obs. Chir. Fasc. 2.*) has opposed this theory, observing, that the staphyloma, for the most part, forms, without the swelling of the cornea having been preceded by any of those morbid dispositions, which are generally considered capable of weakening the texture and elasticity of the cornea; that this membrane, when affected with staphyloma, acquires a much greater thickness than what it has in its natural state, and, consequently, that the staphyloma, far from being concave within, is every where compact and solid; though it ought to be quite the contrary, if the tumour had been occasioned by an immoderate distention, operating on the cornea from within outward, with an absorption of its natural texture.

In regard to this circumstance, says Scarpa, though I would wish to give Richter all the praise, to which he is entitled for his conspicuous merit in every branch of the healing art, I cannot refrain from noticing, that this celebrated author, in pointing out a matter of fact, as he has done, respecting the origin and nature of the staphyloma, has generalized his doctrine too much, by not drawing any line of distinction between the staphyloma of recent occurrence in infants, and that of adult subjects, in whom the disease has acquired so large a volume, as to

protrude considerably beyond the eyelids. I fully agree with Richter, (for it is a certain and demonstrable fact,) that the recent staphyloma in infants is quite compact and solid, on account of the augmented thickness of the cornea in this disease; but it is equally certain, as I have been convinced by repeated observation, that, in this very same staphyloma, originally quite solid and compact, the cornea, strictly speaking, becomes thinner, or, at all events, is not thicker, than in its natural state, after the disease has existed a series of years in adult subjects, and in whom the swelling of the cornea has attained such a size, as to protrude between the eyelids. I wish to imply, that the tumour is not solid throughout, except in regard to its containing, in its amplified state, the iris, the crystalline, and very often, also, a portion of the vitreous humour. These parts, having quitted their natural position, are propelled forward, so as to fill the cavity, which gradually forms in the cornea, and grows larger.

The cornea of infants, in its natural state, is, at least, twice as thick and pulpy as that of adults, and, consequently, the anterior chamber of the aqueous humour, in the former, is comparatively so contracted, to what it is in the latter, that, in infants at the breast, the cornea may be considered as in contact with the iris. In the latter subjects, the softness, flexibility, and succulency of the cornea are naturally such, that, when this membrane is separated from the rest of the eye in the dead subject, and compressed between the fingers, it loses, at least, one half of its volume, and thickness, which does not happen in adults. The cornea of young children is so supple and distensible, that, in minute injections of the head, when the injected matter is copiously extravasated in the eye-ball, the cornea distended from behind forward, elevates itself in the dead subject considerably towards the eyelids; a thing, says Scarpa, that is not observable, under similar circumstances, in the eyes of adults.

To such qualities of the cornea, in children of tender years, and to the natural narrowness of the anterior chamber of the aqueous humour, Scarpa imputes the cause, why ophthalmies in infants so often produce opacity and thickening of this membrane. The cornea swells, becomes preternaturally thickened, and is very soon converted into a pointed, whitish, or pearl coloured tumour, without any cavity internally, and either in perfect contact with, or adherent to, the iris. In the course of years, however, Scarpa remarks, that this disease undergoes new modifications. For, as the whole eye enlarges with age, the iris, and crystalline,

from causes not sufficiently understood, abandon their natural situation, and are incessantly urged forward. This effect is increased, by the very limpid and copious state of the vitreous humour, always existing, when the disease under consideration is inveterate. In this circumstance, whenever the cornea is not completely indurated, and inflexible, the crystalline and iris are insensibly propelled, from within outward, nearer and nearer to the cornea, which they in time distend in all its dimensions, so as to make it project beyond the eyelids, at the same time rendering it thinner in a ratio to the bulk, and magnitude, which it assumes. Scarpa has never met with a voluminous staphyloma, projecting beyond the eyelids in adult persons, which had not originally made its first appearance in infancy; and he has invariably found, that the thickness, and density of the cornea, both in the living, and dead bodies of those, who have been affected with this disease, were in an inverse ratio to the eye. In inveterate cases of staphyloma, forming a large protuberance beyond the eyelids, the iris may here and there be clearly discerned through the diseased cornea, and, if it be not equally manifest at all points of the tumour, it is because the conjunctiva externally spread over the cornea forms, in conjunction with its varicose vessels, on the surface of the tumour, a stratum of matter, not every where equally dense, and opaque. This dense stratum of the conjunctiva, spread over the cornea, easily causes deception, in the staphyloma that has attained a considerable bulk. The more the tumour increases, the more the substance of the cornea seems to become dense and thickened; while, in reality, the contrary happens; for the augmentation in the density of the layer of the conjunctiva, covering the cornea, only partly supplies the diminution in the thickness of the texture of this last membrane. Scarpa thinks it very improbable, that the accurate observers of all ages would have neglected to notice, that the cornea, in this advanced stage of the disease, instead of being thinner, according to the common opinion, is even quite a compact and solid body. Scarpa says, the contrary is recorded in their works, where they speak of the extirpation of thick staphylomas by means of a ligature, and they caution us to tie the thread very gently, lest the cornea, which, in these cases, is very thin, should easily be torn. Gunz relates, that he was an eye-witness of such an accident, which happened to a patient, in whom a staphyloma had been tied by means of a needle, and thread. (*De Staphylom. Dissect. vid. Disput. Chir. Halleri.*)

Scarpa allows, that Richter's doctrine is then a matter of fact, as it relates to the recent staphyloma of infants; but, as far as his own experience goes, it admits of exceptions, in regard to the thickness of the cornea, in the staphyloma of old date, considerable bulk, protruding beyond the eyelids.

Some pretend, says Scarpa, that the sclerotica is also subject to staphyloma, that is, to a partial distention, and prominence of its anterior hemisphere in the white of the eye. Others question the existence of such a disease. Scarpa acknowledges, indeed, that he has never yet met with any tumour, or prominence on the front surface of the sclerotica, corresponding to the white of the eye. On the contrary, what will seem extraordinary and singular, this celebrated surgeon has twice seen, in the dead subject, a staphyloma, in the posterior hemisphere of the sclerotica, a situation, in which it has neither been seen, nor described, by any one, as far as Scarpa knows. The first instance was in an eye, removed for quite another motive, from the body of a woman, forty years of age. This eye was of an oval shape, and altogether larger than the other, which was healthy. On its posterior hemisphere, on the outside of the optic nerve, or the part nearest the temple of the same side, the sclerotica was elevated, in the form of an oblong tumour, resembling a small nut. As the cornea was healthy and pellucid, and the humours still retained their natural transparency, on looking into the pupil of the eye, in question, an unusual brilliancy could be seen at the bottom, formed there by the light passing through that part of the cornea, affected with staphyloma, which had become thinner, and diaphanous. On opening this eye, Scarpa found the whole of the vitreous humour deranged in its organization, and converted into a limpid, aqueous fluid, and the crystalline somewhat yellowish, but not opaque. The posterior hemisphere of the eye being immersed in spirit of wine, to which a few drops of nitrous acid had been added, in order to give to the retina consistence, and opacity, Scarpa could distinctly discern, that the cavity of the staphyloma, in the sclerotica, was not invested with the nervous expansion of the retina; that the choroides, in this place, was very subtile, discoloured, and destitute of its usual reticulated vascularity; and that, in particular, the sclerotica was so much thinned in the situation of the staphyloma, that it was hardly as thick as a sheet of writing-paper. Scarpa learnt, that the woman, from whose body this eye was taken, had some years previously lost the power of seeing with this organ, during the prevalence of an obstinate oph-

thlmy, attended with habitual and excruciating head-achs.

Scarpa had an opportunity of observing a similar disease of an eye, accidentally taken from the body of a woman, thirty-five years of age. It was sent to him from Milan, by Doctor Monteggia. It was of an oval shape, and larger, than its fellow. The staphyloma of the sclerotica was situated on its posterior hemisphere, on the outside of the entrance of the optic nerve, in other words, towards the temple. The vitreous humour was converted into water, the capsule of the crystalline was very turgid, with a limpid, whitish fluid; the lens was yellowish, and smaller, than natural; in the interior of the staphyloma of the sclerotica, the retina was wanting; the sclerotica itself, and the choroides were elevated in the form of a tumour, and rendered so thin, that the light passed through them. Scarpa could not learn any thing concerning the state of this woman's sight; but, in regard to the disease, he much doubts, whether art will ever succeed in administering efficacious means for the stoppage of its progress, much less for its cure.

But, to return to the staphyloma of the transparent cornea, this part of the eyeball being, in this circumstance, affected with an irremediable opacity. Scarpa remarks, that the surgeon can have no other aim in the treatment of this disease, when it is recent in children of ten years, but to hinder the increase of the swelling of the cornea, the organization of which membrane is already destroyed. The tumour must be levelled, and flattened as much as possible; and when the swelling of the cornea is inveterate, very large, and prominent beyond the eyelids, it is to be diminished by surgical means, so as to return within the orbit, sufficiently to permit the deformity of the face to be amended by the application of an artificial eye.

Richter proposes, in cases of recent staphyloma, to make at the bottom of the tumour of the cornea an artificial ulcer, by repeatedly applying the *argentum nitratum*, or the oxygenated muriate of antimony (butter of antimony), and to keep it open by the continued use of the same caustic, with a view of effecting by means of this little issue, the dispersion of the gross tenacious humour, which is the immediate cause of the preternatural opacity, and swelling of the cornea. The author assures us, says Scarpa, that, in this way, he has many times effected a diminution of the staphyloma, and, in one particular case, even restored the transparency of the cornea. This cure has always seemed to Scarpa the most rare, and surprising, of all, that are recorded on the subject of diseases of the eyes; the more so, as this success was obtained in

the space of fourteen days. *Ter repetitâ operatione, quarto scilicet, septimo et decimo die, ne vestigium quidem morbi die decimo-quarto superarat. Obs. Chir. Fasciculus 2.*

Scarpa declares, that though he has frequently attempted to cure the recent staphyloma, in infants, by the above method of making an issue, and this with the greatest confidence of success, and in the persuasion, that this plan of cure was founded on certain, and obvious premises, respecting the nature of the disease, when it is recent, and in children of tender years; though, in doing so, he had for imitation a master in surgery of the highest authority; he has never yet met with such success, as can be at all compared with Richter's either in restoring the transparency of the cornea, or accomplishing a diminution of the volume of the staphyloma. Having formed with the *argentum nitratum* a small ulcer, at the bottom of the cornea, and kept the sore open thirty days and more, he failed in obtaining any benefit, in respect to the diminution, much less the opacity of the cornea, in three infants, one a year and a half old, and the two others somewhat more than three, all which subjects had been recently attacked with staphyloma in one eye, in consequence of the small-pox. A violent chemosis, in a very short time, produced a staphyloma in the eye of a child, five years old. Scarpa made an ulcer at the bottom of the cornea, in the unorganized, swollen substance of which he introduced, for a little depth, the flat part of a lancet. Scarpa kept the sore open, for five weeks, with a solution of the *argentum nitratum*, and he remarked, that the staphyloma became somewhat flatter, so as to lose the acute prominence, which it had at its centre; but the cornea continued as before, every where opaque. Though Scarpa employed the same method in two other subjects, of about the same age, and in the same circumstances; though he kept the ulcer open fifty days, he was never able to effect any depression or diminution of the staphyloma; and, consequently, the pointed, pearl-coloured, projecting part of the tumour continued in the same state as it was before. Scarpa states, that the conical shape, which the cornea assumes in this disease, is a characteristic symptom, by which a staphyloma may be distinguished from the leucoma, with total opacity of the cornea.

If, also, in the course of further trials, partial benefit be found to accrue from this plan, adopted not for the purpose of re-establishing the transparency of the cornea, but for that of merely checking, and diminishing the recent staphyloma in infants, still Scarpa is of opinion, that no one will be easily persuaded, that the

same treatment can ever prove of the least service, in diminishing the size of the large, inveterate, staphyloma in adults; in other words, of that, which projects beyond the eyelids, and rests on the cheek. What advantage can be expected from an artificial ulcer, formed in the substance of the cornea, no longer soft and pulpy, nor merely thickened by a viscid matter, effused in the interstices of its texture, but become dry and coriaceous from time, protruding in consequence of the excessive distention from within outward, and covered with a callous crust, consisting of the layer of the conjunctiva, and its varicous vessels? Certain it is, says Scarpa, that as often as it has happened, that the inveterate staphyloma, protruding out of the eyelids, has accidentally ulcerated from the irritation of any extraneous body, the tears, or long pressure of the parts, on which it rests, the ulcer has never been seen to effect a diminution of the disease; we even read, that the ancient staphyloma, under such circumstances, has often degenerated into a malignant fungus.

Hence, Scarpa observes, that in the highest stage of this disease, when the staphyloma projects beyond the eyelids, art has, at present, no more effectual means for restraining the progress of the complaint, and removing the deformity, than cutting away the staphyloma, and when the place is healed, applying an artificial eye.

Celsus thus expresses himself on the subject of this operation: *Curatio duplex est. Altera ad ipsas radices per medium transuere acu, duo lina ducente, deinde alterius lini duo capita ex superiore parte, alterius ex inferiore adstringere inter se quæ paulatim secando id excidant. Altera in summâ parte ejus ad lenticulæ magnitudinem excindere; deinde spodium, aut cadmiam infricare. Utrolibet autem facto, album ovi lana excipiendum, et imponendum; posteaque vapore aquæ calidæ fovendus oculus, et lenibus medicamentis unguendus est. De Medicina, lib. 7. cap. 7.*

Though, says Scarpa, the first plan or that of the ligature, is at present abandoned, as being generally thought the least appropriate; the majority of surgeons still persevere in passing a needle and ligature, through the lower part of the staphyloma, not for the purpose of tying, or constricting the tumour, it is true, but of making a noose, in order to fix the eye conveniently, when the staphyloma is to be cut off in a circular manner. But Scarpa proves, that the same advantage may be obtained by a very simple method, which is more expeditious, and less incommodious to the patient, and, he is therefore persuaded that the apparatus of the needle and ligature will very soon be disused, both as a means of cure, and an auxiliary in the operation.

With regard to the second method of

removing the staphyloma, or that of excision, Scarpa thinks, that sufficient attention has not hitherto been paid to what Celsus has written on this subject. In fact, Celsus does not forbid cutting away the staphyloma, by a circular incision at its base, as is practised at the present day, but says, that this operation is to be done in the centre, or conical point of the tumour, and that as much of this part of the staphyloma is to be cut away, as will equal a lentil in size: *In summa parte ejus ad lenticulæ magnitudinem excindere*. Scarpa remarks, that the great importance of this precept of Celsus in regard to the successful treatment of the staphyloma, can only be duly appreciated by such as have often had occasion to compare the advantages of Celsus's doctrine, with the serious inconveniences, which result from the common practice of cutting away the staphyloma circularly at its base; and with the evils produced by a semicircular section, comprehending the sclerotica, in Woolhouse's manner, always followed by acute inflammation of the eyeball and eyelids, violent pains in the head, restlessness, spasms, copious and sometimes gangrenous suppurations of the eye and eyelids. To Scarpa it is a matter of fact, proved by a numerous series of observations, that, the more the semi-circular resection of the staphyloma is distant from the centre or apex of the tumour, approximating its base, and advancing towards the sclerotica, the more aggravated are the symptoms consequent to this operation; & *vice versa*.

The following is Scarpa's method of effecting the destruction of the inveterate staphyloma, protruding out of the eyelids. The patient being seated, Scarpa directs an assistant to support his head properly; then taking in his hand a knife, similar to what is used in the extraction of the cataract, he passes the instrument completely across the staphyloma, at the distance of one line and a half, or two lines, from the centre or apex of the tumour, from the external towards the internal angle of the eye, and, by passing the knife forward in the same direction, just as is done in the extraction of the cataract, he makes a semicircular incision downwards, in the most prominent part of the tumour. Having done this, he takes hold of the segment of the staphyloma with the forceps, and turning the edge of the knife upward, he completes the circular resection of the apex of the tumour, in such a way, that the detached portion is one, two, three, or four lines in diameter, according to the size of the staphyloma. As a portion of the iris, adhering to the cornea, from the very commencement of the disease, is commonly included in this section of the pointed part of the tumour, no sooner is the circular division of the apex of the

staphyloma made, than the crystalline, or its nucleus, issues from the eye, followed by a portion of the dissolved vitreous humour. In consequence of this evacuation, continues Scarpa, the eye-ball often diminishes in such a degree, that it can be covered by the eyelids, to which Scarpa immediately applies a pledget of dry lint, supported by a retentive bandage.

The pain, produced by this section, is of the smallest consequence, and it is common to see patients perfectly tranquil, the three, or four first days after the operation. The eye and eyelids most frequently begin to be painful, inflame, and swell, on the fourth day. On the appearance of these symptoms, which ordinarily are very mild, the eye, on which the operation has been done, is to be covered with a bread and milk poultice, in order to promote and accelerate the suppuration of the internal membranes of the eye. When things proceed in a regular manner, the tumefaction of the eyelids subsides about the seventh, or ninth day, and purulent matter is seen on the poultice, blended with the dissolved vitreous humour, which slowly issues from the bottom of the eye. The matter afterwards becomes thick, and whitish, with relief to the patient, and manifest diminution of the whole eye-ball, which not only shrinks within the eyelids, but even sinks into the orbit.

At this period, observes Scarpa, on gently separating the eyelids, the conjunctiva is found swollen, and reddish, and the margin of the wound of the staphyloma seems like a whitish circle. When the detachment of this gelatinous circle takes place, which usually is on the twelfth or fourteenth day after the operation, the edge of the surface, from which the staphyloma was cut, becomes red, contracts, and daily diminishes, so that, at last, the wound is entirely closed. There only remains in the centre of the cornea, for a few days, a small fleshy prominence resembling a little reddish papilla, which, after being touched a few times with the *argentum nitratum*, contracts, and becomes completely healed.

So far, says Scarpa, are alarming symptoms from following this operation, that in a great number of cases, the surgeon is even obliged, several days afterwards, to stimulate the eye, on which it has been performed, in order to make it inflame, partly by leaving it a long while uncovered, and exposed to the air, partly by enlarging the circular resection made in the centre of the staphyloma, of which another circular portion, half a line broad, is removed, in order to facilitate the more abundant discharge of the humours, and the ingress of air into the cavities of the eye, which are so backward to inflame. As soon as inflammation has invaded the interior of the eye, and suppuration has taken place,

the rest of the cure regularly follows under the use of topical emollients, and is soon completed with all possible mildness. As by putting into execution the above method of destroying the staphyloma, the consequent shrinking of the eye-ball takes place equally around the great axis of this organ, the stump, which follows, has also a regular circumference, and presents an easy, and commodious place for the application of an artificial eye. (*Scarpa sulle Malattie degli Occhi.*)

Wenzel and numerous other writers, imply by staphyloma, a protrusion of a piece of the iris, through a wound or ulcer of the eye. See *Iris, Prolapsus of.*

STEATOMA. (from *σταρ*, fat.) A wen, or encysted tumour, containing fat. See *Tumours, Encysted.*

STELLA, or STELLATED BANDAGE. A bandage so named because it makes a cross, or star on the back. It is a roller, applied in the manner of the figure 8, so as to keep back the shoulders. It is often employed in cases of fractures, and dislocations of the clavicle.

STRICTURE. (from *stringo*, to bind.) A diminution, or contracted state of some tube, or duct in the body. See *Urethra, Strictures of*; *Œsophagus*, &c. *Rectum*, &c. Stricture also means, in cases of strangulated hernia, the narrowest part of the opening, or passage through which the bowels protrude, which narrowest part makes on the viscera the pressure causing all the bad symptoms. See *Hernia.*

STRUMA. (from *struo*, to heap up.) Scrofula, or Scrophula. The King's Evil. See *Scrophula.*

STYE. A little inflammatory tumour on the eyelid. See *Hordeolum.*

SUPPRESSION OF URINE. See *Urine, Retention of.*

SUPPURATION. A process, by which a peculiar fluid, termed *pus*, is formed in the substance, or from the surface, of parts of the body.

The article *inflammation* made us understand, that inflammation, when it exceeds a certain pitch, sometimes terminates in suppuration.

When the purulent matter accumulates in the part affected, it is termed an *abscess*, which is distinguished into several kinds, the *acute*, *chronic*, *venereal*, *scrophulous*, &c.

It is observed by Professor Thomson, that the texture, in which suppuration

seems to be most readily produced, by a certain degree of inflammation, is mucous membrane, whether this lines excretory ducts, or canals, or covers the inner surfaces of the respiratory, or urinary organs. In a few hours, after an irritating cause has been applied to these surfaces, the physical and chemical qualities of the fluid, which they secrete in their natural state, are changed. From being a tough viscid substance, not easily miscible with water, the mucus of the nose and bronchia becomes, during an attack of inflammation, very readily miscible with water, of a yellowish white colour, and fluid consistence. If, in this state, the secretion from these membranes be examined with the microscope, it will be found to contain small globules, similar to those which are seen in the blood; and these globules are found to increase in number in proportion to the degree and continuance of the inflammation. We have examples of the production of this pus, or at least of a puriform fluid, in the respiratory organs of persons affected with catarrh, and in the urinary organs of those, who labour under gonorrhœa. In the progress of these diseases, we can generally trace the changes, which take place by slow, but sensible degrees, in the nature of the secretion, from mucus to pus, and from pus back again to the state of mucus. This puriform discharge from mucous membranes, in a state of inflammation, may be kept up for months without these membranes appearing to undergo any other morbid changes, than a slight degree of redness and swelling. A loss of substance, or ulceration, is found not to happen oftener than in one case, out of ten examples of suppuration from mucous membranes. (*Thomson's Lectures on Inflammation*, p. 305—306.)

The same well informed writer afterwards proceeds to explain, that suppuration may be readily produced in the skin, or cutaneous texture, by whatever excites inflammation in that texture, and causes a separation of the cuticle. We have examples of this in blisters from cantharides, and in vesications of the cuticle from superficial burns. If the cuticle, covering a recent blister, or burn, be removed, and the cutis exposed to the irritation of stimulating substances, pus will soon be discharged from the abraded surface. Suppuration can be kept up in cutaneous texture for an indefinite length of time, as we see done every day in the management of perpetual blisters. Ulceration is seldom observed in these cases, and, consequently, in cutaneous texture, loss of substance is by no means necessary for the production of pus.

If the cutis be divided, as in a wound, or a portion of it removed, as in the extirpation of tumours, and either the air, or any other external body, be permitted to re-

main in contact with the divided surfaces, the process of suppuration is speedily induced in the cellular texture subjacent to the skin. After the hemorrhage, which takes place from the small vessels, has ceased, an oozing of a fluid, at first resembling serum, occurs, which is gradually changed into pus. But, in this case, as Dr. Thomson has correctly observed, the surface of the wound is previously covered with a layer of coagulable lymph, which is penetrated with blood-vessels, and gradually raised into the little red eminences, termed granulations.

Appearances similar, though slighter in degree, says Dr. Thomson, are observed in cutaneous suppuration, giving probability to the opinion of Sir E. Home, that, in inflammation, a vascular surface is produced previously to the formation of pus in cellular membrane, and perhaps also in cutaneous texture. Dr. Thomson is inclined to believe, however, that no new vascular surface is generated in the inflammation of mucous membrane. Thus, we see, that in the formation of pus in mucous membrane, cutaneous texture, and exposed cellular substance, no ulceration, no breach of substance occurs; but that, on the contrary, in two of these textures, the cutaneous and cellular, there is an addition made to the parts by the exudation of coagulable lymph, which becomes organized. (*Thomson, p. 305—308.*)

SYMPTOMS OF SUPPURATION.

When matter is fully formed in a tumour, there is a remission of all the symptoms. The throbbing pain, which was before frequent, now goes off, and the patient complains of a more dull, constant, heavy pain. A conical eminence, or *pointing*, as it is termed, takes place at some particular part of the tumour, generally near its middle. In this situation, a whitish, or yellowish appearance is generally observable, instead of a deep red, which was previously apparent, and a fluctuation of a fluid underneath may be discovered, on a careful examination with the fingers. Sometimes, indeed, when an abscess is thickly covered with muscles and other parts, the fluctuation cannot be easily distinguished, though, from other concurring circumstances, there can hardly be the least doubt of there being even a very considerable collection of matter. An œdematous swelling over the situation of deeply situated abscesses is a symptom, which often occurs, and is well worthy the attention of every practical surgeon.

The discovery of the existence of deep abscesses is a circumstance of the highest importance in practice, and one which greatly involves the practitioner's reputation. In no part of the surgeon's employment is experience, in former similar cases,

of greater use to him, than in the present; and however simple it may appear, yet nothing, it is certain, more readily distinguishes a man of observation and extensive practice, than his being able easily to detect collections of deep-seated matter. On the contrary, nothing so materially injures the character and professional credit of a surgeon, as his having in such cases given an inaccurate or unjust prognosis; for, in disorders of this kind, the nature and event of the case are generally at last clearly demonstrated to all concerned.

Together with the several local symptoms of the presence of pus, already enumerated, may be mentioned the frequent shiverings, to which patients are liable on its first formation. However, these rigors seldom occur so as to be distinctly observed, unless the collection of matter is considerable, or situated internally in some of the viscera.

"In the progress of the fever, accompanying acute inflammation, (says Professor Thomson) rigors, or cold shiverings not unfrequently take place, which recur at irregular intervals, and are in general followed by a hot fit, and slight increase of the febrile symptoms. These rigors, or cold shiverings, in general indicate, when they occur in the progress of inflammatory diseases, that pus either is formed, or is about to be so. In inflammation, succeeding to injuries of the head, these rigors are often the first constitutional symptoms which give alarm to the well informed practitioner; for, they are generally, though not always, an indication, that inflammation has already made a dangerous, if not fatal, progress. These rigors also accompany the formation of pus in the viscera contained within the cavities of the chest and belly, and are often the first symptoms, which inform the practitioner, that his endeavours to procure resolution have not been successful." (*See Thomson's Lectures on Inflammation, p. 321.*)

Rigors, as Mr. Hunter remarked, are more common at the commencement of spontaneous inflammations, than in inflammations from external injury. They seldom occur in the suppurations, which follow operations.

The constitutional symptoms, which attend the formation of pus in the progress of chronic suppurations, are generally comprehended under the name of hectic fever. (*See Fevers.*)

The pain, attending what Mr. Hunter termed the suppurative inflammation, is increased at the time when the arteries are dilated, and this gives the sensation called throbbing, in which every one can count his own pulse, by merely paying attention to the inflamed part. Perhaps, this last symptom is one of the best characteristics

of this species of inflammation. When the inflammation is moving from the adhesive state to the suppurative, the pain is considerably increased; but, when suppuration has taken place, the pain in some degree subsides. (*Hunter.*)

The redness that took place in the adhesive stage is now increased, and is of a pale scarlet colour. The part, which was firm, hard, and swelled, in the previous stage of the inflammation, now becomes still more swelled, in consequence of the greater dilatation of the vessels, and the greater quantity of coagulating lymph thrown out. (*Hunter.*)

THEORY OF SUPPURATION.

The dissolution of the living solids of an animal body into pus, and the power of this fluid to continue the dissolution, are opinions, which are no longer entertained by any well informed surgeons of the present day; and the use of such phrases as "*pus corrodes*," "*it is acrid*," &c. expressions, which imply an erroneous way of thinking, is very properly almost entirely discontinued in the language of every sensible medical man. If these notions were true, no sore, which discharges matter, could be exempted from a continual dissolution. Such ideas probably arose from the circumstance of an abscess being a hollow cavity in the solids, and from the supposition, that the whole of the original substance of this cavity was now the matter, which was found in it. This was a very natural way of accounting for the formation of pus by one entirely ignorant of the moving juices, the powers of the arteries, and what takes place in an abscess after it is opened. The knowledge of these three subjects, abstracted from the knowledge of the abscess before its being opened, should have led surgeons to account for the formation of pus from the blood by the powers of the arteries alone. According to the above erroneous principle, abscesses would continue to increase after being opened, as fast as before. Upon the principle of the solids being dissolved into pus, was founded the practice of bringing all indurated parts to suppuration, if possible, and not making an early opening. This was done for the purpose of giving time for the solids to melt down into pus; but, it was apparently forgotten, that abscesses formed matter after they were opened, and, therefore, the parts stood the same chance of dissolution into pus as before. Blinded with the idea, that the solids entered into the composition of pus, the partisans of this doctrine could never see pus flowing from any internal canal, as from the urethra, in cases of gonorrhœa, without supposing the existence of an ulcer in the passage. Such sentiments

might be forgiven, before it was known, that these surfaces could, and generally did, form pus, without a breach of the solids; but, the continuance of this way of thinking now is not mere ignorance, but stupidity. The formation of pints of matter in the cavities of the chest, and abdomen, without any breach in the solids, could not have been overlooked by the most zealous advocates for the doctrine of dissolution. (*Hunter.*)

The moderns have been still more ridiculous; for, knowing, that it was denied, that the solids were ever dissolved into pus, and that there was not a single proof of it, they have been busy in producing what to them seemed a proof. They have been putting dead animal matter into abscesses, and, finding, that it was either wholly, or in part dissolved, they, therefore, attributed the loss to its being formed into pus. This, however, was putting living and dead animal matter upon the same footing, which is a contradiction in itself; for, if the result of this experiment were really what they supposed it to be, the idea of living parts being dissolved into pus must be abandoned, because living and dead animal matter can never be considered in the same light. (*Hunter.*)

It might have been remarked, that even extraneous animal matter would lie in abscesses for a considerable time, without being dissolved, and, that in abscesses arising, either from violence, or from a species of erysipelatous inflammation, there were often sloughs of the cellular membrane, which sloughs would come away, like wet tow, and, therefore, were not dissolved into pus. (*Hunter.*)

It might also have been noticed, that in abscesses in tendinous parts, as about the ankle, a tendon often mortified, and sloughed away, and that the sores would not heal till such sloughs were detached; but though this separation was sometimes not completed, before the expiration of months, yet the sloughs at last were thrown off, and consequently could not be converted into pus. Pieces of dead bone often lie soaking in matter for many months, without being changed into pus; and although bones, so circumstanced, may lose a considerable deal of their substance, a loss which some might impute to the dissolution of the bone into pus, yet, that waste can be accounted for and proved on the principle of absorption. The loss is always upon that surface, upon which the continuity is broken off, and it is a part of the process by which exfoliation of a dead piece of bone is accomplished. The formation of pus has been attributed to a kind of fermentation, in which both the solids and fluids were concerned. This doctrine is easily refuted by stating what happens in internal canals, which naturally secrete

mucus, but frequently form pus, without any loss of substance, or any previous fermenting process. Were we to suppose a fermentation of the solids and fluids the immediate cause of the production of pus, whence could the solids come, which enter into the composition of discharges from the urethra? for the whole penis could not afford matter enough to form the pus, which is discharged in a common gonorrhœa. How also could the fermentation of the solids ever cease? for, there is the same surface secreting its mucus, whenever the formation of pus is discontinued. It may be asked, likewise, by what power the first particle of pus in an abscess, or on a sore, is formed, before there is any particle existing, which is capable of dissolving the solids? An abscess may be stationary for months, and at last be absorbed; what becomes of the fermentation all the while the collection of matter continues stationary?

Extravasated blood has been supposed to be capable of being converted into pus. We find, however, that blood, when extravasated, either from violence, or a rupture of a vessel, as in an aneurism, never of itself becomes pus; nor was pus ever formed in these cases, without being preceded by inflammation. Both the blood and matter are also found together in the same cavity, under such circumstances. If the blood had coagulated, which it seldom does in cases of violence, it would be found still coagulated; and if it had not coagulated, the pus would be bloody.—(Hunter.)

The modern theory of suppuration is, that the matter is separated from the blood by the secreting power of the vessels of the inflamed part, which now acquire a new mode of action.

That pus is formed in the vessels, from which it exudes, by an action of these vessels analogous to secretion, was, so far as I know (says Professor Thomson) first distinctly suggested by Dr. Simpson of St. Andrew's, in his "*Dissertationes de Re Medica*," published in the year 1722. An opinion, similar to that of Dr. Simpson's suggested itself, about the year 1756, to De Haen, from the consideration of what takes place in some cases of phthisis pulmonalis. This author observes, that pus was often expectorated, for a great length of time, by patients affected with phthisis, in whom, after death, no mark of ulceration could be perceived, not even the place in which the pus had been formed. The hypothesis of pus being a secretion was afterwards more fully considered by Dr. Morgan, of Philadelphia, in his inaugural thesis printed at Edinburgh in 1763, entitled "*Puopoeses, sive Tentamen Medicum de Puris Confectione*." The belief, that pus is a secretion, or formed at least by an ac-

tion of the vessels analogous to secretion, was adopted by Mr. Hunter. Indeed, the merit of the original suggestion of this hypothesis has been ascribed to him, though improperly. Bruggman, professor of botany at Leyden, has maintained the same doctrine in an excellent thesis "*De Puogenia*," published in 1785; and it is that which is now very generally taught all over Europe. (See Thomson's *Lectures on Inflammation*; p. 316—317.)

The opinion, that suppuration is a process, analogous to glandular secretion, was at first hastily rejected by many, who were swayed by the fact, that there is no pus ever found blended with the blood in the circulating system. By this mode of reasoning, however, such thinkers must be led to deny the universally received and undoubted doctrine, that the bile is a secretion; and, yet, it is well known, that nothing like this fluid can be detected in an analysis of the blood, and, indeed, a very small quantity would be sufficient to tinge the whole mass of circulating blood with a yellow colour, the same as we see in cases of jaundice. No one would wish to defend the idea of there being either pus, or bile, actually in the circulation; but, only the matter, or modifications of the matter, which, by the combinations, or whatever changes, we may choose to term them, taking place in the secreting vessels, and by their operations are converted into one of the particular fluids in question.

No suppuration ever takes places without being preceded by inflammation; no pus is ever formed but in consequence of it. In abscesses, a suppuration is an immediate effect of inflammation; and when internal cavities remain exposed, no suppuration comes on, till inflammation has formed the disposition and action.

Violence done to parts is one of the great causes of suppuration; but, simply, violence does not always occasion it. The violence must be followed by a prevention of a cure in a more simple way, viz. by a restoration of the structure, so as to carry on the animal functions of the part. The parts must be kept long enough in that state into which they were put by the violence. Or, what is somewhat similar to this, the violence must be attended with death in a part, as, in many bruises, all mortifications and all sloughs, in consequence of the application of caustic, which, when the dead parts separate, leave internal surfaces exposed. (Hunter.)

As every injury, or effect of outward violence, under the above circumstances, is more or less exposed to the surrounding air, the application of air to internal surfaces has been assigned as a cause of suppuration; but, certainly, the air has not the least effect on parts, circumstanced as above, for a stimulus would arise from a wound,

were it even contained in a vacuum. In circumscribed abscesses, the air cannot possibly get to the parts, so as to have any share in making them suppurate.

In cases of emphysema, when the air is diffused over the whole body, no suppuration is the consequence, unless an exposure, or imperfection of some internal surface should be made, for the purpose of allowing the air to escape. A stronger proof, that it is not the admission of air, which makes parts inflame, is, that the cells in the soft parts of birds, and many of the cells and canals of their bones, communicating with the lungs, and always containing air, never inflame; but if these cells are exposed in an unnatural way, then the stimulus of imperfection is given, these cavities then inflame, and their surfaces either form adhesions together, or produce pus. (*Hunter.*)

When the interior of an abscess is examined, the cavity, which contained the matter, is observed to be lined with a smooth, membranous-looking substance, which is of a whitish ash-colour, and has a strong resemblance to coagulating lymph. This membrane-like substance has been termed the *sac*, or *cyst* of the abscess. This sac, or cyst, seems in general to adhere by a vascular union to the surrounding cellular membrane, which is itself likewise denser in texture, and more vascular, than in the natural state, (*Thomson's Lectures*, p. 310.) its cells being closed by coagulating lymph, effused in consequence of that species of inflammation, which Mr. Hunter termed the adhesive. Thus by the formation of a cyst, and the effusion of coagulating lymph in the cellular substance around the abscess, the collection of matter is bounded, and cannot become diffused, as it otherwise would do, in the communicating cavities of the cellular membrane, like the water in œdema.

Something, like this diffusion of pus, seems to occur in erysipelas phlegmonoides. "But, in this case, (says Professor Thomson) the vitality of greater, or less portions of the cellular substance is destroyed, the deadened portions are converted into dirty, whitish, ash-coloured sloughs, and it becomes extremely difficult to say, whether any part of the pus contained in the deadened cellular membrane has been formed in the cells, in which it is contained, or has been absorbed into these cells, after being separated from the parietes of the cavities containing the sloughs themselves." (*Lectures*, &c. p. 310.)

There can be no doubt, that, after an abscess has received a membranous lining, or cyst, the secretion of pus is continued from the surface of the latter part entirely, as well as whatever degree of absorption of the same fluid happens to be going on. In fact, the cysts must be both

secreting and absorbing surfaces. The circumstances which leave no doubt of this point, are the frequent sudden or gradual removal of very large manifest collections of matter; the continual changes occurring in the quantity and consistence of the pus; and the speedy filling of the cavity with purulent matter again after the first contents of the abscess have been discharged.

Another thing, which is yet a subject of controversy, is, whether suppuration ever happens unpreceded by inflammation? Professor Thomson, of Edinburgh, believes, that the affirmative opinion on this point was first suggested by De Haen, of Vienna; but, he thinks, that much of the difference of sentiment in this matter has proceeded from the vague "notions, entertained with regard to the symptoms, which necessarily characterise the state of inflammation, and also with regard to the properties, by which pus is to be distinguished from other animal fluids. Accordingly, in almost all the examples, which De Haen has adduced to prove the formation of pus, without the previous existence of inflammation, he has himself occasion to remark the exudation of coagulating lymph, and the existence of preternatural adhesions; phenomena, which we now know are produced by that state, which Mr. Hunter has denominated adhesive inflammation." But, De Haen uses the term inflammation to express that state, which we denominate ulceration, or ulcerative absorption; for, in speaking of the cases of suppuration, which he has adduced, he observes, that, "in many of them no previous loss, or consumption of substance could be perceived." An observation, similar to this, was made about the same time, or perhaps a little earlier, by Dr. William Hunter, and an account given of it in the second volume of the *London Medical Observations and Inquiries*.

"Mr. Hunter, though he endeavours to establish it as an invariable fact, that no suppuration takes place, which is not preceded by inflammation, is of opinion, that collections of what he terms extraneous matter, something like pus, may form in various parts of the body, without the previous existence of inflammation in the parts, in which it is formed; and accordingly you will find, at page 390 of his *Treatise on Inflammation*, a chapter entitled, "Of Collections of Matter without Inflammation."

Professor Thomson doubts, however, "whether these collections of matter, said to be formed without inflammation, would not have been more properly denominated serophulous abscesses, or chronic suppurations. I am disposed to believe (says he), that, in whatever texture, or organ of the body, serophula manifests itself, there inflammation will be found to exist. The

phenomena, it is true, of inflammation, both local and constitutional, are modified by the existence of the scrophulous diathesis; but, they are, I believe, always present in such a degree as to justify us in giving to them the name of inflammation, and in classing most, if not all local scrophulous affections, among inflammatory diseases. When the indolent swellings, of which Mr. Hunter speaks, occur near to the surface of the body, that part feels warmer, than usual, as may be felt in white-swellings of the joints. The swelling also is either preceded or accompanied with some degree of pain, though, when the affection is internal, the patient may not always be very accurate with regard to the precise seat of this pain. When cut into, the parts also affected with scrophulous swellings are always found more vascular, than usual; in short, all the symptoms occur by which the state of inflammation is characterised." (See *Thomson's Lectures on Inflammation*, p. 313—314.) In another place, this author admits, that the matter, which as formed in chronic suppurations, does not always accurately resemble that, which is formed in acute abscesses; but, yet he contends, that it is so analogous both in its physical and chemical characters, as well as in the circumstances, in which it is produced, that he can see no reason, why it should not be called pus, or a puriform fluid. (P. 315.)

QUALITIES OF PUS.

True pus has certain properties, which when taken singly, may belong to other secretions, but, which, conjointly, form the peculiar character of this fluid, viz. globules swimming in a fluid, which is coagulable by a solution of the muriate of ammonia, which no other animal secretion is, and, at the same time, a consequence of inflammation.

The colour and the consistence of pus are the two qualities which first attract the notice of every, the most superficial observer. The colour arises from the largest portion of this fluid being composed of very small round bodies, very much like those little globules, which, swimming in a fluid, make cream. The fluid, in which the globules of pus swim, we might at first suppose to be the serum of the blood, for it coagulates with heat, like the latter fluid. Pus is also probably mixed with a small quantity of coagulating lymph; as it partly coagulates, after it is secreted.

The fluid part of pus, however, is known to have properties, which serum has not. There being a similarity between pus and milk, experiments have been made to ascertain whether the fluid of pus could be coagulated with the gastric juice of animals; but, no coagulation could be effected

in this manner; a solution of muriate of ammonia made the fluid part of pus coagulate; but, not any other secretion, or natural fluid; and, hence, it was concluded, that whenever globules were found swimming in a fluid, coagulable by muriate of ammonia, the matter was to be considered as pus. (Hunter.)

The proportion, which the white globules bear to the other parts of pus, depends on the health of the parts producing the discharge. When the globules are very abundant, the matter is thicker and whiter, and is called healthy pus; the meaning of which is, that the solids, which produced it, are in good health; for, these appearances in the matter are no more, than the result of certain salutary processes going on in the solids, the effect of which processes is to produce the disposition, on which both suppuration and granulation depend. (Hunter.)

Pus is specifically heavier than water, and is probably about as heavy as blood.

Besides the above properties, pus has a sweetish mawkish taste, very different from that of most other secretions, and the same taste takes place, whether it is pus from a sore, or an irritated inflamed surface.

Pus has a smell, in some degree peculiar to itself; but this differs in different cases. Some diseases, it is said, may be known by the smell, as for instance, a gonorrhœa.

Pus sinks in water; mucus floats. Pus communicates to water an uniformly troubled white colour; mucus gives the appearance of stringy portions floating in it. Mucus is said to be more readily dissolved by sulphuric acid, than pus is. It has also been asserted, that if water be added to such solutions, the pus is precipitated to the bottom of the vessel; while the mucus, instead of being completely precipitated, forms swimming flakes. A solution of caustic alkali dissolves both pus and mucus; but, when water is added, the pus is said to become separated, but not the mucus.

Though solutions in chemical menstrua and precipitations, have been thought a test of the distinction, between these two fluids; yet, the method has been thought absurd and unphilosophical. It has been conceived, that all animal substances whatever, when in solution, either in acids or alkalies, would be in the same state, and therefore, that the precipitation would be the same in all. Calcareous earth, when dissolved in muriatic acid, is in that acid in the same state, whether it has been dissolved from chalk, limestone, marble, or calcareous spar, and precipitations from all are the same. Hence, experiments were made on organic, animal matter, such as muscle, tendon, cartilage, liver, and brain;

and on inorganic, such as pus and the white of an egg. All these substances were dissolved in sulphuric acid, and precipitated with the vegetable alkali. Each precipitation was examined with such magnifiers, as plainly shewed the forms of the precipitates, all which appeared to be flaky substances. The precipitate by the volatile alkali had exactly the same appearance. The same appearances were seen, when the above kinds of animal matter were dissolved in the vegetable caustic alkali, and precipitated with the muriatic acid. A flaky substance, void of any regular form, composed each precipitate. (*Hunter.*)

Pus does not irritate the particular surface, which secretes it, though it may be very irritating to any other. Hence, no suppurating surface of any specific kind, can be kept up by its own matter. If this had not been the case, no sore of a specific quality, or producing matter of an irritating kind, could ever have been healed. This is similar to every other secretion of stimulating fluids, as the bile, tears, &c. which fluids do not stimulate their own glands, or ducts, but are capable of stimulating any other part of the body. (*Hunter.*)

Whenever a real disease attacks, either the suppurating surface, or the constitution, the production of true pus ceases, and the fluid becomes changed in some measure, in proportion to these morbid alterations. In general it becomes thinner and more transparent, and it partakes more of the nature of the blood, as is the case in most other secretions under similar circumstances. *Sanies* is the term usually applied by surgeons, to pus, in this degenerated state. This unhealthy sort of matter has more of the serum, and, frequently, more of the coagulating lymph in it, and less of the combination, which renders it coagulable by a solution of muriate of ammonia. It has also a greater proportion of the extraneous parts of the blood, which are soluble in water, such as salts; and it has a greater tendency, than true pus, to become putrid. Such unhealthy matter may even be irritating to the surface, which produces it.

The discharge, when of an irritating sort, is more stimulating to the adjoining parts with which it comes in contact, than to its own secreting surface. In this manner, it frequently produces excoriation of the skin, and ulceration. Thus the tears excoriate the skin of the cheek, in consequence of the quantity of salts, which they contain. From this effect, matter has been called corrosive, a quality, which it has not; the only property which it possesses, being that of irritating the parts, which it touches, so as to cause their absorption. (*Hunter.*)

When the vessels thus lose the power of producing good pus, they also lose more or less the power of forming granulations. This may depend on some deviation from the due structure, and action, which such vessels should possess, in order to be qualified for the performance of these two operations.

Pus, from several circumstances, would appear in general to have a greater tendency to putrefaction, than the natural juices have; but, perhaps, this is not the case with pure pus, which, when first discharged from an abscess, is commonly perfectly sweet. There are, however, some exceptions to this, but these depend on circumstances entirely foreign to the nature of pus itself. Thus, if the abscess had any communication with the air, while the matter was confined in it; or if the collection has been so near the colon, or rectum, as to have been infected by the feces, then we cannot wonder, that the matter should become putrid. When blood is blended with pus; when sloughs are mixed with it; when the parts forming the seat of the abscess, are in a gangrenous state from an erysipelatous affection; the matter has a greater tendency to putrefy, than the pure pus, discharged from sound abscesses, or healing sores. Pure matter, though easily rendered susceptible of change, by extraneous additions, is in its own nature tolerably uniform and immutable. It appears so unchangeable, that we find it retained in an abscess for weeks, without having undergone any alteration. These qualities, however, only belong to perfect pus. If a healthy sore inflames, the matter, now produced from it, though unmixed with extravasated blood, or dead solids, becomes much sooner putrid, and much more irritating, than the discharge, formed before this alteration of the ulcer. (*Hunter.*)

In the preceding paragraph, it is stated, that matter remains very often unchanged in abscesses for weeks. This expression of Hunter's is not strictly correct; for, it is well known, that the surfaces of the cavities of abscesses are always absorbing, as well as secreting ones; consequently, there must be a continual mutation going on in the contained matter.

When there are diseased bones, or other extraneous bodies, exciting irritation, sometimes even in so great a degree as to make the vessels bleed, and often wounding the vessels of the part, the matter is always found to be very offensive. This state of the discharge is one mark of a diseased bone.

The discharge of an unhealthy sore blackens silver probes, and preparations of lead. This effect is imputed by Dr. Crawford to the sulphurated hydrogen

gas, generated in the matter. (*Phil. Trans.* vol. 80. Year 1790, p. 385.) Further interesting observations on the nature of pus may be found in an Essay on the Differences between Pus and Mucus, by Dr. Darwin, junior; also in Dr. G. Pearson's Paper in *Philos. Trans.* 1811.

USE OF PUS.

By some it is supposed to carry off humours from the constitution. Suppuration is sometimes regarded as a constitutional disease, changed into a local one, which constitutional malady is discharged, or thrown out of the body, either in the form of pus, or together with this fluid. Critical abscesses have been thought to be cases of this sort. Suppuration has also been imagined to carry off local complaints from other parts of the body, on the old principle of derivation, or revulsion. For this reason, sores or issues are made in sound parts before allowing other sores to be dried up. Suppuration is sometimes excited with a view of making parts, such as indurated swellings, dissolve into pus; but, we have endeavoured to shew, that no dissolution of the solids is concerned in the production of pus.

A secretion of pus is looked upon as a general prevention of many, or of all, the causes of disease. Hence, issues are made to keep off both universal as well as local diseases. However, the use of pus is perhaps unknown; for, it is formed most perfectly from healthy sores, and in healthy constitutions; and large discharges from parts not very essential to life, produce very little change in the constitution, and as little upon being healed up, whatever some may suppose to the contrary. (*Hunter.*)

This is certainly the case with many old ulcers, the suppuration from which seems to have little, or no effect, in impairing the health. Nor is there any real reason to be afraid of healing such ulcers, when possible, lest a worse disease should follow from the stoppage of a discharge, to which the system is supposed to be habituated so much, that the continuance of it must be essential to health.

Every one knows, that when there is no interference of art, that is, when the surface of a sore is left uncovered, the thin part of the matter evaporates, and the thick part dries and forms a scab. Nature, therefore, seems to have designed, that one use of pus should be to make a cover, or protection, for ulcerated surfaces. But I cannot agree with what has been asserted (*Hunter*), that the natural healing of a sore under a scab takes place more quickly, than when surgical dressings are employed.

Among the secondary uses of suppuration, may be mentioned, opening a communication between a disease and the external surface of the body; forming a passage for the exit of extraneous bodies, &c.

TREATMENT WHEN SUPPURATION MUST TAKE PLACE.

In cases of inflammation, arising from accident, but so circumstanced, that we know suppuration cannot be prevented, the indication is to moderate the inflammation, which, if the powers are great, and the injury done considerable, will probably be very violent. If the constitution should also be much affected, certain general means are proper, such as bleeding, purging, and nauseating medicines. While the constitution continues to be disturbed, suppuration cannot take place in the most favourable manner. In these cases, also, such medicines as produce a gentle perspiration greatly relieve the patient, for instance, the pulv. ipecac. comp.; antimonials; aq. ammon. acet.; saline draughts, &c. Opium may produce a temporary diminution of action; but, it is not always the consequence of this medicine, as there are constitutions, which it renders more irritable, and of course where it aggravates the inflammatory action.

The applications to inflammations, which are to suppurate and form an abscess, commonly used, are poultices and fomentations. These, however, appear to be applied without much critical exactness, or discrimination; for, they are applied before suppuration has taken place, and when this event is not desired; and they are also applied after suppuration has taken place. With respect to suppuration itself, abstracted from all other considerations, the indication cannot be the same in every state; but if poultices and fomentations are found to be of real service in the two stages of the disease, there must be something common to both, for which they are of service, independently of simple suppuration. Poultices are useful, when the inflammation attacks the skin, either in the first instance or after an abscess has approached so near the skin, that this becomes secondarily affected. This benefit appears to arise from the skin being kept soft and moist. Such is the use of a poultice in inflammation, either before or after suppuration, until the abscess is opened. But, when poultices and fomentations are applied to inflamed parts, in which we wish to avoid suppuration, reason and principle will not justify the practice, though such applications may be proclaimed by experience to be very proper. (*Hunter.*)

**TREATMENT AFTER SUPPURATION HAS
TAKEN PLACE.**

When suppuration cannot be stopped, or resolved, it is in general to be promoted.

How far suppuration can be increased by medicines, or applications, is doubtful; but attempts are generally made, and, for this purpose, suppurating cataplasms and plasters, composed of the warm gums, seeds, &c. have been recommended. Mr. Hunter doubted, whether such applications had any considerable effect in the way intended; for, if they were put on a sore, they would hardly increase the discharge from it, and, perhaps, even diminish it. However, in many cases, in which the parts are indolent, and hardly admit of true inflammation, in consequence of which a perfect suppuration cannot take place, stimulating the skin brings on a more salutary inflammation, and of course a quicker inflammation.

These applications have been found, however, to bring the matter more quickly to the skin, even in the most rapid suppurations. This effect has been mistaken for an increased formation of pus; but, this consequence can only follow in cases, in which the inner surface of the abscess is within the influence of the skin. The accelerated progress of the matter to the surface of the body arises from another cause, viz. the promotion of ulceration in the parts, between the collection of matter, and the cuticle.

Emollient poultices are commonly applied to inflamed parts, when suppuration is known to have taken place. These can have no effect upon suppuration, except that of lessening the inflammation, or rather making the skin more easy. The inflammation must have reached the skin before poultices can have much effect, for they can only affect that part. The ease of the patient, however, should be considered, and we find, that fomentations and poultices are often beneficial in this way. By keeping the cuticle moist and warm, the sensitive operations of the nerves of the parts are soothed. On the contrary, if the inflamed skin is allowed to dry, the inflammation is increased, and as suppuration is probably not checked by the above treatment, it ought to be put into practice. As warmth excites action, the fomentation should be as warm as the patient can bear, without inconvenience. (*Hunter.*)

"The local treatment in phlegmonous abscesses (as Professor Thomson observes) is still more simple, than that by which we endeavour to procure resolution. It consists almost solely in the application of a moderate degree of warmth

and moisture to the inflamed part, either by means of fomentations, or poultices. The manner in which these means act in promoting suppuration is unknown. Independently of their temperature, it seems very doubtful, whether fomentations and poultices have any power of promoting suppuration in the parts, to which they are applied. They keep the cuticle moist and warm, they promote perspiration, they sooth and allay pain in many inflammations, and these are probably the only immediate effects, which they produce. The rest is the work of nature. In suppurations, attended by very severe pain, the use of warm fomentations is often found to afford singular relief, not only by their effect in easing pain, but also by their seeming to shorten the duration of the suppurative stage. In the cases of suppuration, in which they give relief, they should be repeated every four or six hours. The most common way of employing them, is by wringing linen, or woollen cloths, out of warm water, and applying these to the inflamed part, of as high a temperature as the feelings of the patient can bear. Decoctions of herbs were formerly much employed in the way of embrocation, and were then, and are still by many practitioners, supposed to possess peculiar virtues in promoting suppuration. Whether embrocations with the narcotic herbs might not in some cases be beneficial, by producing a sedative effect in allaying pain, I am unable to say, though I am inclined to believe, that even they act chiefly by their warmth and moisture. In cases where you find it necessary to use an embrocation with herbs, the flowers of camomile may in general be substituted in place of the leaves or flowers of almost every other plant. These flowers readily imbibe and retain moisture. They are, when moist, of a soft consistence, and can be easily moulded to the figure of the parts, to which they are applied." (*Thomson's Lectures, p. 333.*) Oatmeal, crumb of bread, and especially linseed meal, are the ingredients mostly preferred in this country for emollient poultices. When bread is used, it is generally boiled in milk. The observations, however, which we have offered on poultices in another place, are all now equally applicable. (*See Inflammation.*)

**OF THE TIME WHEN ABSCESSSES SHOULD BE
OPENED.**

As abscesses, wherever formed, must increase that part of their cavity, which is next to the skin, more quickly than the bottom, they must become, in some

degree, tapering towards the latter part, with their greatest breadth immediately under the skin. This shape of an abscess, when allowed to take place, is favourable to its healing, for it puts the bottom, which is the seat of the disease, more upon a footing with the mouth of the abscess, than it otherwise could be. As the bottom, or part, where the abscess began, is more or less in a diseased state; and as the parts between the seat of the abscess and the external surface are sound parts, having only allowed a passage for the pus, they, of course, have a stronger disposition to heal, than the bottom has.

To keep the mouth of an abscess from healing before its bottom, the collection of matter should be allowed to break of itself; for, although abscesses in general only open by a small orifice, more especially when sound, yet, in such cases, the skin over the general cavity of the matter is so thinned, that it has very little tendency to heal, and often ulcerates and makes a free opening. If the latter event should not spontaneously occur, it may now be more easily obtained by the interference of the surgeon.

Abscesses, which are the most disposed to heal favourably, are the quickest in their progress to the skin, and the matter comes to the surface almost at a point; the swelling is not so conical as in other cases, and when it bursts, the orifice is exceedingly small. On the other hand, when there is an indolence in the progress of the abscess, the collection spreads more, or distends the surrounding parts in a greater degree, in consequence of their not being so firmly united by inflammation, in the one as they are in the other instance; nor will ulceration so readily take the lead, and the matter will come to the skin by a broad surface, so as to thin a large portion of the cutis. (*Hunter.*)

It may certainly be set down as a general axiom, that all phlegmonous abscesses should be allowed to break, and not be opened by the surgeon. When punctured unnecessarily, or prematurely, they never heal so favourably as when left to themselves.

Particular cases, however, should be opened, as soon as the existence of matter is ascertained. Abscesses should only be allowed to burst of themselves, when the confinement of the matter can do no mischief. Abscesses in the abdomen, or thorax, under the cranium, in the eye, and joints, should be mostly opened very soon. When suppuration takes place beneath ligamentous expansions, or aponeuroses, which invariably retard the progress of the matter to the surface of the body, an early opening should be made. If this be not done, the matter spreads to a great extent, separating such ligamentous expansions from the

muscles, and the muscles from each other, and, as the pus cannot get to the surface of the body, the length of the disorder is of course increased. When matter is so situated, as to be liable to insinuate itself into the chest, or abdomen, or into the capsular ligaments of the joints, it is highly proper to prevent this extension of mischief, by making a timely opening into the abscess.

"Those abscesses ought to be opened early (says Professor Thomson), that are situated in parts, through which the matter is liable to become widely diffused. This is particularly the case with abscesses, that are situated on the forepart of the neck, or in the cavity of the axilla, or by the side of the rectum. When matter is formed in the cavity of the axilla, if it does not speedily obtain an external outlet, it is very liable to pass up towards the clavicle in the course of the axillary plexus of nerves and vessels, or forwards under the pectoral muscle. I have repeatedly seen axillary abscess take both of these directions at the same time, forming one of the most painful and difficult cases to treat, which occurs in the management of abscesses." Dr. Thomson also considers an early opening proper and necessary, where the matter is lodged, as in some cases of whitloe, in the sheaths of the tendons; where matter is formed under the periosteum; where it collects under fasciæ, or in the vicinity of large arteries, joints, or the greater cavities of the body: also when the abscess is deep-seated. (See *Thomson's Lectures on Inflammation*, p. 336-338.)

With respect to making an early opening into abscesses, situated near large arteries, I am not aware, that any danger of the artery ulcerating in consequence of the nearness of the pus really exists. Therefore, some doubts may reasonably be entertained of Professor Thomson's advice in this particular case, as the general rule of opening abscesses near large blood-vessels, in an early stage of the disease, would be objectionable on the ground of the practice exposing the vessels themselves to injury. Indeed, this well-informed writer distinctly mentions, in considering the subject in question, that the arteries are not very susceptible of ulcerating absorption.—(P. 337.)

OF THE PLACE WHERE THE OPENING SHOULD BE MADE.

If a free opening is not required, or making one is not practicable, it is at least proper to make whatever opening can be made in a depending situation. By this means the matter will more readily escape, and all pressure arising from the confinement or lodgment of pus, will be prevented. A very small degree of pressure on that side of the abscess

which is next to the skin, may produce ulceration there; and although such pressure might not, in many cases, be so great as to produce ulceration at the bottom of the abscess; yet it may be sufficiently great to prevent granulations from forming on that side, and thereby retard the cure, as no union can take place, but by means of granulations. The pressure is always most, and retards the formation of granulations in the greatest degree, at the most depending part of the abscess. Hence, if no opening be made in this situation, the upper part of the abscess readily heals to a small point, which becomes a fistula.

When circumstances forbid making an opening at the most depending part of an abscess, perhaps, nothing more can be done, than to evacuate the matter as often as necessary, and gently to compress the sides of the abscess together, when the situation of the case admits of the practice.

But abscesses are not always to be opened at the most depending part. The distance between the matter and the skin at this part is the common reason against the method. If an abscess is rather deeply situated, and points in a place which is higher than where the collection lies, it is proper to make the opening where the conical eminence, or, as it is termed, the *pointing*, appears. Thus, if an abscess should form in the centre of the breast, and point at the uppermost part, which is often the case, it would be improper to cut through the lower half of the mamma, in order to make a passage for the matter in that direction. If an abscess should form on the upper part of the foot, it would be wrong to make an opening through the sole of the foot to get at the most depending part of the abscess; for, besides cutting such a depth of sound parts, a great many useful ones would be destroyed.

When the abscess does not point in a depending situation, as in the instances just cited, since the place where the matter threatens to open a passage is likely to be the future opening, and this situation is disadvantageous to the healing of the deep part of the abscess, it is generally best to let the collection of matter first burst of itself, and then dilate the opening as freely as necessary. By allowing abscesses to burst spontaneously, the opening is not so apt to heal as if made by art, and, therefore, is better in such situations. (*Hunter.*)

In most cases, it is more advantageous even to cut through a certain thickness of parts, for the sake of obtaining a depending opening, than to make an opening, where the pointing appears, that is, where the parts are thinnest, and the matter nearest the surface. This remark is highly worthy of remembrance, when there is no doubt of

the existence of matter at the depending place, and when the parts to be divided are not important ones. Collections of matter beneath the fasciæ of the fore-arm and thigh particularly demand attention to this direction, as they commonly point where those ligamentous expansions are thinnest, not where the matter can most readily escape.

Abscesses in the sheath of the rectus abdominis should also be opened in a low situation.

DIFFERENT METHODS OF OPENING ABSCESSSES.

All abscesses will naturally burst of themselves, unless the matter be absorbed, and, in general, they ought to be allowed to take this course. There are, however, as we have already explained, particular circumstances which require an early opening; but, when the skin over the abscess is very thin, it is not of so much consequence, whether the case be permitted to burst of itself, or it be opened by the surgeon.

When abscesses are large, it is generally necessary to open them by art, whether they have burst of themselves or not; for, the natural opening will seldom be sufficient for the completion of a cure; and, although it may be sufficient for the free discharge of the matter, yet these abscesses will heal much more readily when a free opening is made; for, the thin skin over the cavity granulates but indifferently, and therefore unites but slowly with the parts underneath. (*Hunter.*)

Abscesses may be opened either by an incision, or by making an eschar with caustic. To the latter plan, however, many urge strong objections: the use of caustic is not usually attended with any advantage which may not be obtained by a simple incision; upon a tender inflamed part it gives much more pain; it is more slow in its effects; and the surgeon can never direct the operation of the caustic so accurately as to destroy exactly the parts which he wishes, and no more. If the eschar be not made deeply enough, the lancet must, after all, be used. Caustic also leaves, after its application, a disagreeable scar, a consideration of some importance in opening abscesses about the female neck or face. To these numerous objections we have to add, that the eschar is, very frequently, ten or twelve tedious days in becoming detached.

When there is a redundance of skin, or when there is a good deal of it thinned, however, an opening made with caustic will answer, perhaps, as well as an incision. The application of a caustic may also sometimes be advantageously resorted to when there is a good deal of

indolent hardness around a small abscess.

The *calx cum potassa*, or the *potassa* alone, is the best caustic for opening abscesses. The part is first to be covered with a piece of adhesive plaster, which has a portion cut out exactly of the same figure and size as the opening intended to be made in the abscess. The best way of making the eschar, is to dip the end of the caustic in water, and to rub it on the part till the skin becomes brown. The active substance is then to be immediately washed off with some wet tow, the plaster is to be removed, and an emollient poultice applied.

In almost all cases, it is better to use the lancet, or double-edged bistoury. Either of these instruments opens the abscess at once, and with less pain, than results from the use of caustic; it occasions no loss of substance, consequently a smaller cicatrix; and, by using it, the opening may be made in the most advantageous direction, and of the exact size required.

DRESSINGS AFTER OPENING ABSCESSSES.

When an abscess has burst of itself, and it is unnecessary to enlarge the opening, all that is requisite is to keep the surrounding parts clean. The continuation of the same kind of poultice, which was before used, is, perhaps, as good a practice as any; and when the tenderness, arising from the inflammation, is over, lint and a pledget may be made use of, instead of the poultice.

But, an abscess, opened by a cutting instrument, is both a wound and a sore, and partakes more of the nature of a fresh wound in proportion to the thickness of the parts cut. Hence, it is necessary that something should be put into the opening to keep it from healing by the first intention. If it is lint, it should be dipped in some salve, which will answer better than lint alone, as it will allow of being taken out sooner. This is advantageous, because such sores should be dressed the next day, or, at latest, on the second day, in order that the pus may be discharged again. When the cut edges of the opening have suppured, which will be in a few days, the future dressings may be as simple as possible, for nature will, in general, complete the cure.

If the abscess has been opened by caustic, and the slough has either been cut out or separated of itself, the case is to be regarded altogether as a suppurating sore, and dressed accordingly.

Perhaps, dry lint is as good a dressing as any, till the nature of the sore is known. If it should be of a good kind, the same dressing may be continued; but, if not, then it must be dressed accord-

ingly. Parts, which at first appear to be sound, sometimes assume every species of disease, whether from indolence, from irritability, from scrophulous, and other dispositions. This tendency to disease arises, in some cases, from the nature of the parts affected, as, for instance, bone, ligament, &c. (Hunter.)

Consult particularly Mr. John Hunter's *Treatise on the Blood, Inflammation, and Gunshot Wounds*, a work, in which more interesting knowledge respecting Abscesses and Suppuration is contained, than in any other one ever published. See also *Traité de la Suppuration de F. Quesnay*, 1749. Various parts of the *Mémoires de l'Académie de Chirurgie*. *L'Encyclopédie Méthodique*, Partie Chirurgicale, article *Abscès*. *Dissertations on Inflammation* by John Burns, 1800. E. Home's *Dissertation on the properties of Pus*, 1788; and his *Pract. Obs. on Ulcers*, 2d Edit. 1801. C. Darwin's *Experiments, establishing a criterion between mucilaginous and purulent matter*, &c. Lichfield, 1780. Several parts of Pott's *Chirurgical Works*, but especially his *Treatise on the Fistula in ano*. Richter's *Anfangsgründe der Wundarzneykunst*, Band 1, Kap. 2. Callisen's *Systema Chirurgiæ Hodiernæ* in many places. Dr. J. Thomson's *Lectures on Inflammation*, p. 305, &c. Edinb. 1813; a work, in which a profound knowledge of medical science, and of surgery in particular, is every where conspicuous. Pearson's *Principles of Surgery*; p. 34, &c. Edit. 2. Lassus *Pathologie Chirurgicale*, Tom. 1, p. 21, &c. &c. Edit. of 1809. Dr. G. Pearson's *Obs. and Experiments on Pus in the Philosophical Trans.* for 1811.

SURGERY, or CHIRURGERY, (derived from *chirurgion*, from *χειρ* the hand, and *τεχνον*, work), has been by many considered to be that branch of medicine, which principally effects the cure of diseases by the application of the hand alone, the employment of instruments, or the use of topical remedies. (*Encyclopédie Méthodique*, Partie Chir. Tom. 1, Art. *Chirurgie*.) But, although this definition certainly conveys to us some idea of the nature of this most useful profession, it is not entirely accurate as applied to the present state of practice. It might indeed be correct during that short unfavoured period of surgery upon the continent, some centuries ago, when its practice was denounced by the Council of Tours, as unfit for the hands of priests and men of literature, and when the surgeon became little better than a sort of professional servant to the physician, the latter alone not only having the sole privilege of prescribing internal medicines, but even that of judging and directing when surgical operations should be performed. Then the subordinate surgeon was only called upon to execute with his knife, or his hand, duties, which the more exalted physician did not choose to undertake; and, in fact, he visited the patient,

did what was required to be done, and took his leave of the case, altogether under the orders of his master. In modern times, however, the good sense of mankind has discovered, that surgery is deserving of an eminent rank amongst such arts as ought to be cultivated for the general benefit of society; that the man, who is not himself accustomed to the performance of operations, cannot be the best judge of their safety and necessity; and, that, in every point of view, the surgical practitioner merits as much favour and independence in the exercise of his profession, as he whose avocation is confined to physic. Hence, the surgeon is now exclusively consulted about many of the most important diseases, to which the human body is liable. Being no longer under the yoke of the physician, he follows the dictates of his own judgment and knowledge; he prescribes whatever medicines the case may demand, internal as well as external; and under the encouragement of an enlightened age, he sees his profession daily becoming more scientific, more respected, and more extensively useful.

By some writers, physic is said to have for its object the treatment of internal, surgery that of external diseases. This definition, however good and plausible it may at first appear, can only be received with numerous exceptions in regard to modern surgery: for instance, the psoas abscess; stone in the bladder; an extravasation of blood within the skull in consequence of accidental violence; are universally allowed to be strictly chirurgical cases; yet, no man in his senses would call these disorders external.

Others have defined surgery to be the mechanical part of physic, "*quod in therapeia mechanicum*;" but, although this has obtained the assent of so eminent a modern surgeon, as Professor Richerand, of Paris, (*Dict. des Sciences Medicales*, Tom. 5, p. 85.) I believe few on this side of the water will be of his opinion. As Mr. John Pearson has observed: "Many people have imagined, that when a man has learnt the art of dressing sores, of applying bandages, and performing operations with a little dexterity, he must necessarily be an accomplished surgeon. If a conclusion so gross and fallacious had been confined to the vulgar and illiterate, the progress of scientific surgery would have suffered little interruption; but if young minds are directed to these objects, as the only important matters upon which their faculties are to be exercised; if the gross informations of sense constitute the sum of their knowledge, little more can be expected from such a mode of study, than servile imitation, or daring empiricism. Indeed,

some people have affected to oppose surgery as an art to medicine as a science; and if their pretensions were justly founded, the former would certainly be degraded to a mere mechanical occupation. But, it is not very easy to comprehend the grounds of such a distinction. The internal and external parts of the body are governed by the same general laws during a state of health; and, if an internal part be attacked with inflammation, the appearances and effects will bear a great similarity to the same disease situated externally; nor are the indications of cure, in general, materially different. If by science, therefore, be meant "a knowledge of the laws of nature," he who knows, what is known of the order and method of nature, in the production, progress, and termination of surgical diseases, merits as justly the title of a scientific practitioner, as the well-educated physician. The practical parts of physic and surgery are very frequently disunited; but, their theory and principles are indivisible, since they truly constitute one and the same science." (*Pearson's Principles of Surgery, Preface.*)

But, though we can object on good grounds to the above-mentioned definitions of surgery, it seems impossible to offer any other, against which equal objections could not be brought. In fact, how is it possible to define surgery with any degree of accuracy, until the boundaries between it and physic can be determined? Richerand talks indeed of the Medical School of Paris having now successfully established the limits and objects of surgery, and he boasts of this as an original improvement reflecting credit on his countrymen. (See *Dict. des Sciences Med.* T. 5, p. 88.) Yet, what are we to think, when we remember, not only that he has, in the commencement of the very same article, defined surgery to be "*quod in therapeia mechanicum*," but that by way of illustrating what the Parisian School has accomplished, he says, that surgery was first demonstrated by it to be only a means of physic, and not a separate and distinct science? (See also *Dict. des Sciences Med.* article *Chirurgicales, Maladies.*)

As a learned Professor notices, the limits between physic and surgery are not very precisely marked, and the respective functions of the physician and surgeon, long as those names have existed, are still but very inaccurately defined. "The most superficial acquaintance with the symptoms, progress, and termination, of the various morbid affections to which the human body is liable, must be sufficient to convince every unprejudiced enquirer, that there is but a slight foundation, if indeed there be any, for this distinction, in the nature of the diseases, which these practitioners are required

to treat, or in the modes of treatment, by which the diseases themselves may be cured, or relieved. Experience has long shewn, that the use of internal remedies is not only required in a large proportion of the diseases, which are regarded as strictly chirurgical, but, also, that there are few diseases, which come under the care of the physician, in which, morbid affections, requiring the manual aid, or practical skill of the surgeon, do not frequently occur.

“The treatment of febrile and internal inflammatory diseases, it will be allowed, belongs exclusively to the province of the physician, wherever the distinction between physician and surgeon has been introduced, and is rigidly observed; yet, in some species of fevers, and in all internal inflammatory diseases, blood-letting is often the principal, if not the only remedy that is required. But, this is an operation, however urgent the necessity for it be, which from engagement the physician cannot, and from the fear of degrading his province of the profession, will not perform. Retention of urine not unfrequently takes place in symptomatic febrile diseases, and this is an affection, which does not always yield to the use of internal remedies; but, it is an affection also, from the painful uneasiness, which it immediately excites, as well as from the danger, which it threatens, that will not admit of delay. When internal remedies, therefore, fail in relieving the patient, the urine must be speedily drawn off by means of a chirurgical operation; otherwise inflammation, mortification, and rupture of the bladder, must necessarily ensue. Febrile and internal inflammatory affections terminate not unfrequently in the formation of fluids, which it is necessary to let out by a chirurgical operation; and abscesses, fistulous openings, and ulcers are formed, which require the aid of the surgeon. In patients, also, affected with severe febrile diseases, from being long fixed down to their beds in one position, some of the parts of the body, upon which they rest, occasionally acquire a disposition to mortify, larger or smaller portions of the skin and subjacent cellular membrane becoming dead, separate from the living parts, and sores are formed, which are but too often the subject of unavailing chirurgical practice. To employ, in the different stages of this species of mortification, from its first commencement to the complete separation of the dead parts, and the formation of a new skin, the appropriate external and internal remedies, requires a greater share of chirurgical skill, than can reasonably be expected in those who make a profession solely of physic. Unhappy, therefore, must be the lot of that patient,

who, in circumstances similar to those which I have described, has the misfortune to have for his sole medical attendant, a physician ignorant of surgery.

“But (continues Professor Thomson), if a knowledge of surgery be necessary to the student, who intends to practise physic, the knowledge of physic, on the other hand, is no less necessary to him, who intends to devote his attention exclusively to the profession of surgery; for, indeed, there are few chirurgical diseases, which are not in some period, or another, of their existence, accompanied by morbid affections of the same nature with those, which fall properly and most frequently under the care of the physician. It will only be necessary to mention, as examples of these affections, the symptomatic fever, which attends inflammation, whether this affection has been induced by external injury, or has occurred spontaneously in the body from internal disease; the hectic fever, supervening to long continued processes of suppuration; the febrile state, and other morbid affections, which are sometimes brought on by the too sudden and injudicious use of mercury; bilious fevers, and the various derangements of the digestive organs, which are sometimes the cause, and at other times the consequence, of local diseases; the nervous affections, such as apoplexy, convulsions, paralysis, and mania, which arise not unfrequently from injuries of the head; and locked jaw, or tetanus, which, in warm climates particularly, is so very liable to be induced by punctured wounds. These are morbid affections, the proper study and treatment of which, when they occur, without local injury, are supposed to belong to the physician, rather than the surgeon; but, occurring very frequently as they do in chirurgical diseases, and always modifying, or aggravating the effects of these diseases, ignorance of their nature, relations, and modes of cure, is not only inexcusable, but highly criminal in the practitioner, who ventures to undertake their treatment.” (*Thomson's Lectures on Inflammation, Introduction.*)

From what has been stated, I think it very certain, that there never can be a complete scientific division of the healing art into physic and surgery; and that all attempts to distinguish the numerous diseases and injuries of the human body into medical and surgical cases, must in a great measure be decided by custom, and the mutual agreement of practitioners, rather than by any rules, or principles, which are at all consistent.

In the earliest periods, the same men cultivated the whole field of medicine. The writings of Hippocrates, Galen, Celsus, Paulus Ægineta, Albucasis, &c.

prove, that the Greeks, Romans, and Arabians never had an idea of the human body being susceptible of only two classes of diseases, one of which formed the province of physic, while the other constituted a separate and distinct science called surgery. All these ancient authors treat successively of fevers, fractures, wounds, and nervous diseases, and none of them appear to have supposed, that there could be any disorders, which really deserved to be called *external* and others *internal*. About the middle of the twelfth century, however, the Council of Tours prohibited the ecclesiastics from undertaking any bloody operation. Surgery was then rejected from the universities, under the empty pretext, "*Ecclesia abhorret sanguine*," often expressed, in its decrees, as Professor Thomson well observes, but never acted upon, except in this instance, by the church of Rome. It is to this epoch that we must refer the true separation of physic from surgery, the latter being abandoned to the laity, who, in those ages of barbarism, were totally illiterate.

It is an observation made by the celebrated Bichat, that two things are essentially necessary to form a great surgeon, viz. genius and experience. One traces for him the way; the other rectifies it; both reciprocally assist in forming him. Without experience, genius would be unprofitably fertile; without genius, experience would only be a barren advantage to him. (*Œuvres Chir. de Desault par Bichat, Tom. 1. Discours Prelim.*) Out of the large number of hospital surgeons, who are to be met with in every country of Europe, and who enjoy ample opportunities of profiting by the lessons of experience, how few distinguish themselves, or ever contribute a mite to the improvement of their profession. Opportunity, without talents and an aptness to take advantage of it, is not of more use, than light to a blind man. On the other hand, splendid abilities, without experience, can never be enough to make a consummate surgeon, any more than a man with the greatest genius for painting can excel in his particular art, without having examined and studied the real objects, which he wishes to delineate. In short, as a sensible writer has remarked, "*Les grands chirurgiens sont aussi rares, que le génie, le savoir, et les talents.*" (*Mém. de l'Acad. de Chir. Tom. 1. Pref. p. 41. Edit. 12mo.*)

The description of the qualities, which a surgeon ought to possess, as given by Celsus, is excellent as far as it goes. A surgeon (says he) should be young, or, at any rate not very old; his hand should be firm and steady, and never shake; he should be able to use his left hand with as much dexterity as his right; his sight

should be acute and clear; his mind intrepid and pitiless, so that when he is engaged in doing any thing to a patient, he may not hurry, nor cut less than he ought, but finish the operation, just as if the cries of the patient made no impression upon him. (*A. C. Celsi Med. Præf. ad lib. 7.*)

"By the word "*immisericors*," as Richerand has observed, (*Nosogr. Chir. Tom. 1. p. 42, Edit. 2.*) Celsus did not mean, that a surgeon ought to be quite insensible to pity; but, that during the performance of an operation, this passion should not influence him, as all emotion would then be mere weakness. This undisturbed coolness, which is still more rare than skill, is the most valuable quality in the practice of surgery. Dexterity may be acquired by exercise; but, firmness of mind is a gift of nature. Haller, to whom nature was so bountiful in other respects, was denied this quality, as he candidly confesses. "Although (says he) I have taught surgery seventeen years, and exhibited the most difficult operations upon the dead body, I have never ventured to apply a cutting instrument to a living subject, through a fear of giving too much pain." (*Bibl. Chir. 1775, Tom. 2.*)

Surgery may boast of having had an origin, that well deserves to be called noble; for, the earliest practice of it arose from the most generous sentiment which nature has implanted in the heart of man, viz. from that sympathetic benevolence, which leads us to pity the misfortunes which we behold, and inspires us with an anxious desire to alleviate them. He who first saw his fellow creature suffer could not fail to participate in the pain, and endeavour to find out the means of affording relief. Opportunities of exercising this useful inclination were never wanting. In the first ages of the world, man in his destitute state was under the necessity of earning, by force, or stratagem, a subsistence which was always uncertain, and in the combats into which this sort of life drew him, he frequently met with wounds, and other injuries. The consequence was, that he began at a very early period to pay attention to the mode of curing such accidental hurts. Wars, by multiplying wounds, at the same time increased the necessity for assistance, and enhanced its value. Kings themselves then did not disdain to dress wounds, and several of the warriors sung by Homer, derived not less renown from their skill in surgery, than their valour in war. Such were Chiron, Machaon, and Podalirius.

In fact, amongst the ancients, the profession of medicine and surgery constituted a sacred kind of occupation, and the practice of it belonged only to privileged persons. Esculapius was the son of Apollo,

In the armies, the highest princes gloried in dressing the wounds of those, who had fought the battles of their country. Amongst the Grecians, Podalirius, Chiron, and Machaon, were not only distinguished for their valour, but also for their skill in surgery, as we learn from the poem of the immortal Homer. The value which was placed upon the services of Machaon by the Grecian army may well be conceived from the anxiety which they evinced to have him properly taken care of, when he was wounded in the shoulder with a dart. "O Nestor, pride of Greece, (cries Idomeneus) mount, mount upon thy chariot! and let Machaon mount with thee! Hasten with him to our ships; for, a warrior who, like he, knows how to relieve pain, and cure wounds, is himself worth a thousand other heroes." (See *Iliad*, lib. xi.) Hippocrates was one of the first citizens of Greece; he nobly refused all the rich offers of several kings, enemies of his country, to entice him into their service; and, in particular, he disdained to accept those of Xerxes, whom he regarded as a barbarian.

It is in the immortal poems of the *Iliad* and *Odyssey*, that we find the only certain traditions respecting the state of the art before the establishment of the republics of Greece, and even until the time of the Peloponnesian war. There it appears, that surgery was almost entirely confined to the treatment of wounds, and that the imaginary power of enchantment was joined with the use of topical applications.

In the cures, recorded in the sacred writings of the Christian religion, the intervention of a supernatural power is always combined with what is within the scope of human possibility. The same character evinces itself in the infancy of the art in every nation. The priests of India, the physicians of China and Japan, and the jugglers of the savage or half civilized tribes of the old and new continents, constantly associate with drugs and manual operations certain mysterious practices, upon which they especially rely for the cure of their patients. Such was also, no doubt, the character of the medicine of the Egyptians in the remote times, previous to the invention of the alphabet, and upon which so very little light is now thrown.

It is curious, however, to find from some late observations made by the men of science, who accompanied the French expedition to Egypt in 1798, that amongst the ruins of ancient Thebes there are documents, which fully prove, that surgery in the early times of the Egyptians, had made a degree of progress, of which few of the moderns have any conception. It is noticed by Larrey, that, when the celebrated French General Desaix had driven

the mamalukes beyond the cataracts of the Nile, the Commission of Arts had an opportunity of visiting the monuments of the famous Thebes, and the renowned temples of Tentyra, Karnack, Medynet Abou, and Luxor, the remains of which still display their ancient magnificence. It is upon the ceilings and walls of these temples, that basso-relievos are seen representing limbs that had been cut off with instruments very analogous to those which are employed at the present day for amputations. The same instruments are again observed in the hieroglyphics, and vestiges of other surgical operations may be traced, proving, that in these remote periods, surgery kept pace with the other arts, which had already attained a high degree of perfection. (See *Larrey's Mémoires de Chirurgie Militaire*, Tom. 1, p. 233; and Tom. 2, p. 223.)

We next come to the epoch, when by the union and arrangement of scattered facts, the science truly arose. Hippocrates, born in the island of Cos, four hundred and sixty years before the common æra, collected the observations of his predecessors, added the results of his own experience, and composed his first treatises. In the hands of this great genius, medicine and surgery did not make equal progress. The former reached the highest degree of glory. Hippocrates drew up the history of acute diseases in so masterly a style, that twenty past centuries have hardly found occasion to add any thing to the performance. But, surgery was far from attaining the same degree of perfection. The religious veneration for the asylums of the dead, and the impossibility of dissecting the human body, formed an insurmountable obstacle to the study of anatomy. An imperfect acquaintance with the structure of animals reputed to bear the greatest resemblance to man, could only furnish venturesome conjectures, or false inferences. These circumscribed notions sufficed for the study of acute diseases. In these cases, the attentive observation of strongly marked symptoms, and the idea of the operation of a salutary principle, derived from remarking the regular succession of such symptoms, and their frequently beneficial termination, enlightened the physician in the employment of curative means; while surgery, deprived of the assistance of anatomy, was too long kept back in an infant state. Whatever praises may have been bestowed on those parts of the works of Hippocrates particularly relating to surgery, and which amount to six in number (*de officina medici; de fracturis; de copitis vulneribus; de articulis vel luxatis; de ulceribus; de fistulis;*) when compared with his other acknowledged legitimate writings, they appear only as the rough sketches of a picture by a great master.

Excepting the fragments, collected or cited by Galen, we possess no work written by any of the successors of Hippocrates until the period of Celsus; which leaves a barren interval of almost four centuries. In this space lived Erasistratus, as well as Herophilus, celebrated for the sects which they established, and, particularly, for having been the first who studied anatomy upon the human body.

Celsus lived at Rome in the reigns of Augustus, Tiberius, and Caligula. He appears never to have practised the healing art, on which however he has written with much precision, elegance, and perspicuity. His work is the more precious, inasmuch as it is the only one, which gives us information with regard to the progress of surgery in the long interval between Hippocrates and himself. The four last books, and especially the seventh and eighth, are exclusively allotted to surgical matter. The style of Celsus is so elegant, that he has generally been regarded quite as the Cicero of medical writers, and long enjoyed high reputation in the schools. His surgery was entirely that of the Greeks, notwithstanding he wrote at Rome; for, in that capital of the world, physic was then professed only by persons who had either come from Greece, or had received instruction in the celebrated schools of this native soil of all the arts and sciences.

Let us pass over the interval which separates Celsus and Galen. This latter was born at Pergamus in Asia minor, and came to Rome in the reign of the emperor Marcus Aurelius. He practised surgery and physic there about the year 165 of the christian era, (*Galen. Opera Omnia*, 1521. Edit. Aldi, 5 vols. in fol.) These two sciences were at that time still united, and though some writers of much earlier date speak of the division of physic into dietetical, surgical, and pharmaceutical, no such distinction was followed in practice. As Galen had been a surgeon at Pergamus, he continued the same profession at Rome; but being soon attracted by the predominating taste of the age, in which he lived, for a science, which more easily yields to the systems and dazzling speculations of philosophical sects, he afterwards neglected surgery which strictly rejects them. His writings prove, however, that he did not abandon it entirely. His commentaries on the treatise of Hippocrates, *De Officina Medici*, and his essay on bandages and the manner of applying them, shew that he was well versed even in the minor details of the art. Besides it is known, that he paid great attention to pharmacy, and, in his work upon antidotes, chapter 13, he tells us himself, that he had a drug shop in the via sacra, which fell a sacrifice to the flames, that destroyed, in the reign of Commodus, the

temple of peace, and several other edifices.

To Galen succeeded the compiler Oribasius, Œtius of Amida, a physician, who lived towards the close of the fifth century, Alexander of Tralles, and Paulus Œgineta, so called from the place of his birth. This last collected into one work, still justly esteemed, all the improvements, which had been made in surgery up to his own time. Paulus concludes the series of Greek and Roman physicians, and he may be looked upon as the last of the ancients, unless it be wished to let the Arabians have a share in the honours of antiquity. Paulus practised at Rome and Alexandria. Afterwards the downfall of surgery followed that of all the other sciences, and from the capture of Alexandria by the Saracens under Amrou, viceroy of Egypt, in 641, until the end of the tenth century, nothing prevailed but the dark clouds of ignorance and barbarism.

Masters of a great part of the Roman empire, the Arabians dug up the Greek manuscripts, which lay buried under the ruins of the libraries; translated them; appropriated to themselves the doctrines which they contained; impoverished them with additions; and transmitted to posterity only enormous compilations. In a word, such are the treatises of Rhazes, Hali-Abbas, Avicenna, Averrhoes, and Albucasis, the most celebrated of the Arabian authors. Inventors of a prodigious number of instruments and machines, they appear to have calculated the efficacy of surgery by the richness of its arsenals, and to have been more anxious to inspire terror than confidence. As an instance of the cruelty of their methods, we shall merely notice, that, in order to stop the bleeding after amputation of a limb, they were in the habit of plunging the end of the stump into boiling pitch.

The fate of medicine was not more fortunate. In vain, the school of Salerno, founded about the middle of the seventh century, made some attempts to revive its splendour. Medical science being seated on the same benches, where the doctrine of Aristotle, accommodated to religious opinions, was the subject of endless controversies, imbibed, as it were by contagion, the argumentative and sophistical mania, and became enveloped in the dark hypotheses of scholastic absurdity. (*Richerand, Nosographie Chirurgicale*, Tom. 1.)

The universal ignorance, (continues this author); the pretended horror of blood; the dogma of a religion, which shed it in torrents for useless quarrels; an exclusive relish for the subtleties of the school, and speculative theories; are circumstances, further explaining the profound darkness, which followed these empty labours. About the middle of the twelfth century

(1163), the Council of Tours prohibited the ecclesiastics, who then shared with the Jews the practice of medicine in christian Europe, undertaking any bloody operation. It is to this epoch, that the true separation of medicine from surgery must be referred. The latter was abandoned to the laity, who in those ages of barbarism were almost all entirely unlettered and destitute of education. The priests, however, still retained that portion of the art, which abstained from the effusion of blood. Roger, Rolandus, Bruno, Gulielmus, de Salicetus, Lanfranc, Gordon, and Guy de Chauliac, confined themselves to commentaries on the Arabians, and mutilated surgery by reducing it almost entirely to the use of ointments and plasters. Guy de Chauliac, however, the last of the Arabians, must be excepted from this censure. His work, written at Avignon in 1363, in the pontificate of Urban the fifth, whose physician he was, continued to be for a long while, the only classical book in our schools. It may be observed, that as he imitated in every respect the other Arabian physicians, and like them thought that it did not become an ecclesiastic to deviate from the austerity of his profession, he has passed over in silence the diseases of women.

Antonius Benevenius, a physician of Florence, was the first who perceived, that the compilations of the ancients and Arabians ought to be relinquished for the observation of nature. (*De abditis rerum causis, Florent. 1507, in 4to.*) A new era now began. The moderns saw, that, by treading servilely in the footsteps of their predecessors, they could never succeed in equalling them. The labours of Vesalius gave birth to anatomy. Illuminated by this science, surgery, the restoration of which had been already prepared by the works of some Italian physicians, put on a different appearance in the hands of Ambroise Paré, the first and most eminent of the French surgeons.

Obeing the dictates of his genius, Paré made authority yield to observation, or sought to reconcile them, when envy, busily intent on persecuting him, represented his discoveries as a crime. Although he was the restorer, if not the inventor, of the art of tying the blood-vessels, he was compelled to make imperfect extracts from Galen, and alter the text, in order to rob himself, in favour of the ancients, of the glory, which this distinguished improvement deserved.

Surgeon of King Henry the second, Francis the second, Charles the ninth, and Henry the third, of France, he practised his profession in various places, followed the French armies into Italy, and acquired such esteem, that his mere presence in a besieged town, was enough to reanimate those employed for its defence. In the

execrable night of Saint Bartholomew, his reputation saved his life. As he was of the reformed religion, he would not have escaped the massacre, had not Charles the ninth himself undertaken to protect him. The historians of those days (*Mém. de Sully*) have preserved the remembrance of this exception, so honourable to him who was the object of it; but, which should not diminish the just horror, which the memory of the most weak and cruel tyrant must ever inspire. "Il n'en voulut jamais sauver aucun (says Brantome) sinon maistre Ambroise Paré, son premier chirurgien, et le premier de la chrétieneté; et l'envoya quérir et venir le soir dans sa chambre et garderobe, lui commandant de n'en bouger; et disait qu'il n'était raisonnable qu'un qui pouvait servir à tout un petit monde, feust ainsi massacré."

Ambroise Paré was not content, like his predecessors, with exercising his art with reputation; he did not follow the example of the Quatre-Maitres; of Pitard, so justly celebrated for having composed the first statutes of the College of Surgeons at Paris, in the reign of St. Lewis, whom he had attended in his excursions to the Holy Land; and of several other surgeons, the fruits of whose experience were lost to their successors. Paré transmitted the result of his own experience in a work that will remain immortal. (*See Œuvres d'Ambroise Paré, Conseiller et premier Chirurgien du Roi, divisées in 28 livres, in folio. Edit. 4to. Paris, 1535.*)

His writings, so remarkable for the variety and number of facts in them, are eminently distinguished from all those of his time, inasmuch as the ancients are not looked up to in them with superstitious blindness. Freed from the yoke of authority, he submitted every thing to the test of observation, and acknowledged experience alone as his guide. The French writers are with reason proud of their countryman Paré to this day: they allege, that he must ever hold amongst surgeons the same place that Hippocrates occupies amongst physicians. Nay, they add, that, perhaps, there are none either of the ancients, or moderns, who are worthy of being compared with him. (*Richerand Nosographie Chirurg. Tom. 1.*)

After the death of this great man, surgery, which owed its advancement to him, continued stationary, and even took a retrograde course. This circumstance is altogether ascribable to the contemptible state, into which those who professed the art fell, after being united to the barbers by the most disgraceful association.

Pigrai, the successor of Ambroise Paré, was far from being an adequate substitute for him. A spiritless copier of his master, he abridged his surgery in a Latin work, where the unaffected graces of the original,

the sincerity, and the ineffable charm, inseparable from all productions of genius, entirely disappeared. He received, however, equal praise from his cotemporaries; doubtless, because he filled a high situation: but, as Richerand remarks, his name, which is to-day almost forgotten, proves sufficiently, that dignities do not constitute glory.

Rousset and Guillemeau distinguished themselves in the art of midwifery; while Covillard, Cabrol, and Habicot enriched surgery with a great number of curious observations. (See *Obs. Chir. pleines de remarques curieuses*, Lyon, 1639, in 8vo. *Alphabet Anatomique*, Genève, 1602, in 4to.; and *Semaine Anatomique; Question Chir. sur la Bronchotomie*, Paris, 1620, in 8vo.)

In the next or seventeenth century, the same impulse produced additional improvements. Then appeared in Italy Cæsar Magatus, who simplified the treatment of wounds, (*de rarâ vulnerum medicatione*, libri 2, Venet. 1616, in folio); Fabricius ab Aquapendente, even less praiseworthy as a surgeon than as a physiologist, (*Opera Chir.* Paris, 1613, in fol.); and Marcus Aurelius Severinus, that restorer of active surgery. (*De efficaci Medicina*, libri 3, Francfort, 1613, in folio. *De Recondita abscessuum natura* libri 7, Neapoli, 1632, in 4to. and *Trimembris Chirurgia*, &c. Francfort, 1653, in 4to.) Amongst the English surgeons flourished Wiseman, who was the Paré of England, (See *Several Chirurgical Treatises*, London, 1676, in fol.); and William Harvey, whose discovery of the circulation of the blood had such an influence over the advancement of surgery, that he must be classed among the principal improvers of this science. (See *Exercitatio Anatomica de motu cordis et sanguinis in animalibus*, Francofurti, 1653, in 4to.) In Germany, Fabricius Hildanus, (*Obs. et Curationum*, Centuriæ 6, 2 vol. in 4to. 1641.) This Fabricius was far superior to the other. Scultetus, so well known for his work entitled *Armentarium Chirurgicum*, Ulmæ, 1653, in folio. Purmann and Solingen, who had the fault of being too partial to the use of numerous complicated instruments. (See *Cursus Obs. Chir.* Lipsiæ, 1710, in 4to. *Manuale Obs. der Chirurgie*; Amsterdam, 1684, in 4to.)

Holland, restored to liberty by the generous exertions of its inhabitants, did not remain a stranger to the improvement of surgery. This nation, so singular in many respects, presents us with one particularity, which claims the notice of a medical historian. Ruysch, who was an eminent anatomist, and merits equal celebrity for his *Obs. Anatomico-Chirurgicarum Centuriæ*, Amsterdam, 1691, in 4to. carried with him to the grave the secret of his admirable injections. (See also his *Thesaur. Anat.* x in 4to. *Adversariorum anatomicorum medico-chirurgicorum Decad.* 3. in 4to. Amsterdam.)

Roonhuysen also made a secret of his lever, which, before the invention of the forceps, was the only resource in difficult labours. Raw, who successfully cut fifteen hundred patients for the stone, took such pains to conceal his manner of operating, that Heister and Albinus, his two most distinguished pupils, have each given a different explanation of it. Such a disposition, which was extremely hurtful to the advancement of surgical knowledge, would materially have retarded the progress of surgery in Holland, had not Camper, in the following century, effaced this imputation by the great number of his discoveries, and his zealous desire to make them public.

While these improvements were going on in Italy, England, and Holland, surgery languished in a humiliated state in France: The accoucheur Mauriceau (*Traité des Maladies des Femmes grosses*, Paris, 1668, in 4to.) Dionis, (*Cours d'Opérations de Chirurgie*, Paris, 1707, 8vo.), Saviard, (*Nouveau Recueil d'Obs. Chir.* Paris, 1702, in 12mo.) and Belloste, (*Chirurgien d'Hôpital*, Paris, 1696, in 8vo.) were the only French surgeons of note, who could be contrasted with so many distinguished men of other nations. Richerand observes, that the splendid days of Lewis the 14th were an iron age for discouraged surgery. And yet this monarch seems to have been personally interested in the melioration of this important art; for he was very nearly falling a victim to a surgical disease, a fistula in ano; and was not cured, till after a great number of blundering operations, and useless experiments.

Chronology teaches simply the history of dates. In the study of the sciences, the only method of impressing the memory with facts, consists in connecting the epoch of them with the learned men by whom they have been illustrated. But, the greatest surgeons of the eighteenth century have not altered the face of their profession, although they have powerfully contributed to its advancement. In surgery, as an author has remarked, some feeble rays always precede brilliant lights, and it approaches perfection in a very gradual way. In the last century, however, amongst the distinguished surgeons of France, there are two of extraordinary genius, round whom, as it were, all the others might be grouped and arranged, and whose names deserve to be affixed to the two most brilliant epochs of French surgery. These are first J. L. Petit, whose glory has been shared by the Academy of Surgery; and, secondly, the celebrated Desault.

It is not with surgery, as with physic, strictly so called: the epochs of the latter are distinguished by hypotheses; while those of surgery are marked by discoveries. The eminent men in this last branch of

the profession have not, like the most renowned physicians, created sects, built systems, destroyed those of their predecessors, and constructed a new edifice, which in its turn has been demolished by other hands. All of them have been satisfied with combating ancient errors, discovering new facts, and continuing their art, the sphere of which they have enlarged by their discoveries, without making it bend under the yoke of systems, which it would have ill supported. To this steady and uniform course (says Richerand), which is a striking proof of the superiority of surgery, and of the certainty and invariableness of its principles, shall we oppose the numerous revolutions of physic? The Christian religion, which abounds in sects, has not more of them, than physic. "Naturistes, solidistes, humoristes, vitalistes, animistes, semi-animistes, mécaniciens, chimistes; le plus grand nombre des médecins honore Hippocrate d'un culte presque superstitieux; ceux-ci marchent sous les bannières de Staahl; ceux-la s'appuient du grand nom de Bøerhaave; tels autres invoquent Sydenham, Hoffmann, Stoll, absolument comme les théologiens combattent pour Luther, Zuingle, Calvin, ou Jansen." (*Nosogr. Chir. Tom. I.*)

The eulogy on J. L. Petit, delivered in the midst of the Royal Academy of Surgery, of which he was one of the first and most distinguished members, represents him as blending the study of anatomy with his amusements when a boy; and ardently seeking every opportunity to increase his knowledge by observation. He had had experience enough to publish at an early period of his life his *Traité sur les Maladies des Os*, Paris 1705, in 12mo. a work, which for a century was esteemed the best upon the subject. It may be noticed, that his success was opposed most virulently by the envious critics. It was not till after more than thirty years of academical labours and extensive practice, that he was unanimously elected as the head of his associates. This acknowledged superiority was the more flattering, as J. L. Petit obtained it at a period when surgery was in a flourishing state in France, and when he held no place from which he could derive an influence foreign to his personal merit. While Mareschal, La Peyronie, and La Martiniere assured him of the royal favour, Quesnay, Morand, and Louis, who corrected his writings, made him speak a language which does honour to that famous collection to which he contributed his observations, (see *Mémoires et Prix de l'Académie Royale de Chirurgie*, 10 vols. in 4to.) and in which, if we except some theoretical explanations, nothing has lost its value by age. In short, it will ever be considered as one of the most valuable collections of surgical knowledge.

J. L. Petit was also the author of a "*Traité des Maladies Chirurgicales et des Opérations qui leur conviennent. Ouvrage Posthume*;" a production that will always stand high in the estimation of the judicious surgeon.

The history of this epoch, so glorious for the profession of surgery, is completely detailed in the *Memoirs and Prix* of the Royal Academy of Surgery, a work which is absolutely indispensable, and the various parts of which cannot be too often considered. In it are preserved the labours of Le Dran, Garengeot, de la Faye, Louis, Verdier, Foubert, Hevin, Pibrac, Fabre, Le Cat, Bordenave, Sabatier, Puzos, Levret, and several other practitioners, who, though less famous, have contributed by their exertions and knowledge to form this useful body of surgical facts. The preceding surgeons also distinguished themselves by other productions.

Le Dran published:

1. *Parallèle des différentes manières de tirer la Pierre hors de la Vessie*, 1 vol. in 12mo.
2. *Opérations de Chirurgie*, 2 vols. in 12mo.
3. *Observations de Chirurgie*, 2 vols. in 12mo.
4. *Traité des Plaies d'Armes à feu*, 1 vol. in 12mo.

Garengeot wrote:

1. *Traité des Instrumens de Chirurgie*, 2 vols. in 12mo.
2. *Traité des Operations de Chirurgie*, 3 vols. in 12mo.

Fabre was the author of

1. *Recherches sur l'Art de Guérir*, 1 vol. in 8vo.

Lecat wrote:

1. *Recueil des Pièces sur l'Operation de la Taille*.

Sabatier published the

1. *Médecine Opératoire*, 3 vols. in 8vo.

Puzos composed:

1. *Traité des Accouchemens*. Paris, 1759, in 4to.

Levret wrote:

1. *Observations sur les Accouchemens Laborieux*, Paris, 1747.
2. *Art des Accouchemens, démontré par les principes de Physique*, Paris 1761, in 8vo.
3. *Essai sur l'Abus des Regles Generales, &c.* Paris 1766, in 8vo.
4. *Observations sur la Cure Radicale des Polypes*, Paris, 1749.

To the foregoing list of eminent French surgeons must be added the names of La Motte, Maître-Jean, Goulard, Daniel, Ravaton, Mejean, Pouteau, David, and Frère Cosme.

La Motte published:

1. *Traité Complet des Accouchemens naturels, non-naturels, et contre nature*.
2. *Traité Complet de Chirurgie*.

Maître-Jean was the author of

1. *Traité des Maladies de l'Œil*, 1 vol. in 4to.

Goulard wrote:

1. *Œuvres de Chirurgie, Liege 1763, 2 vols. in 12mo.*

Ravatton composed :

1. *Le Chirurgien d'armée.*

Pouteau :

1. *Mélanges de Chirurgie, 1 vol. in 8vo.*

2. *Œuvres Posthumes, 3 vols. in 8vo.*

David :

1. *Observations sur la Nécrose. Paris 1782, in 8vo.*

While surgery was thus advancing in France, other nations were not neglectful of it. At this period, flourished in England, White, Cheselden, Douglas, the two Monroes, Sharp, Cowper, Warner, Alanson, Percival Pott, Hawkins, Smellie, and the two Hunters.

White's *Cases in Surgery, 1770*; Cheselden's *Treatise on the High Operation for the Stone, London 1723, in 8vo.* and his *Treatise on the Anatomy of the Human Body*; Douglas's tract, entitled, "*Lithotomia Douglassiana*;" Sharp's *Treatise of the Operations*; and his "*Critical Enquiry into the present State of Surgery*;" Monro's *Works* by his son; Warner's *Cases in Surgery, 1754*, and his *Description of the Eye and its Diseases, 1775*; Alanson's *Treatise on Amputation*; Pott's *Chirurgical Works*; Smellie's *Midwifery*; and John Hunter on the *Blood, Inflammation, &c.*; his *Treatise on the Venereal Disease*; *Animal Economy*; the *Teeth*; and all the papers written by himself and his brother, in the *Phil. Trans. Med. Obs. and Inquiries*, and *Trans. of a Society for the Improvement of Med. and Chir. Knowledge*; are productions which reflect the highest credit on the state of surgery in England.

But, of all these eminent men, none contributed more powerfully than Mr. Percival Pott, to the improvement of the practice of surgery in England. His life, indeed, forms a sort of epoch in the history of the profession. Before his inculcations and example had produced a desirable change, the maxim of "*dolor medicina doloris*," as we learn from Sir James Earle, remained unrefuted. The severe treatment of the old school, in the operative part and in the applications, continued in force. The first principles of surgery, the natural process and powers of healing, were either not understood, or not attended to; painful and escharotic dressings were continually employed; and the actual cautery was in such frequent use, that at the times, when the surgeons visited the hospital, it was regularly heated, and prepared as a part of the necessary apparatus. Where shall we find more sensible, or more truly practical observations on the treatment of abscesses, than in his excellent treatise on the fistula in ano? Where shall we meet with better remarks on the local treatment of gangrenous parts, than in his valuable tract on the mortification of the toes and feet? What author abounds with so many just observations on injuries

of the head, blended it is true with rather too great a partiality to the trepan, the so frequent necessity for which is now less generally acknowledged? His description of the inflammation and suppuration of the dura mater, and of the treatment, is matchless. The account, which he has left us of the disease of the vertebræ, attended with paralysis of the limbs, is perhaps his most original production. His celebrated essay on fractures was also very original, and has had in this country considerable influence over the treatment of these injuries; but, there can now be no doubt, that the effects of position were exaggerated in this part of his writings, and that surgeons ought still to make every possible exertion to render their apparatus for broken bones more effectual. (See *Fractures*.) A more really valuable production of this eminent surgeon is his remarks on amputation. The necessity for that operation in certain cases is there convincingly detailed; and the most advantageous period for its performance clearly indicated. The urgency for its early execution, after particular injuries, he has indeed so perfectly explained, that the late inculcations on the subject by Larrey, and several other modern surgeons, appear to be in a great measure anticipated, the only difference being that Pott's remarks applied principally to compound fractures, while Larrey's refer to gun-shot wounds. All these, however, are cases of accidental violence, and of course, must be treated upon the same general principles.

A longer comment on the writings and improvements of Percival Pott would here be requisite to do him every degree of justice; but, his name, advice, and opinions are so conspicuous throughout this volume, that I shall be excused for not saying any thing more in the present place, than that he was in his time the best practical surgeon, the best lecturer, the best writer on surgery, the best operator, of which this large metropolis could boast.

Another character of still greater genius and originality, though of inferior education, was the ever memorable John Hunter, surgeon to St. George's Hospital, who was at once eminent as a surgeon, an anatomist, a physiologist, a naturalist, and a philosopher. If Pott materially improved many parts of the practice of surgery in England, and evinced himself to be the most skilful operator of his time, John Hunter was also not less importantly employed in extending the boundaries of physiological knowledge, and in the investigation of human, and particularly comparative anatomy. The knowledge which he derived from his favourite studies, he constantly applied to the improvement of the art of surgery, and he omitted no opportunity of examining morbid bodies, by

which means, he collected facts, which are invaluable, as they tend to explain the real causes of the symptoms of numerous diseases.

In the practice of surgery, whenever operations proved inadequate to their intention, Mr. Hunter always investigated with uncommon zeal the causes of ill success, and in this way, he detected many fallacies, as well as made some important discoveries in the healing art. He ascertained the cause of failure, common to all the operations in use for the radical cure of the hydrocele, and was enabled to propose a mode of operating attended with invariable success. He ascertained, by experiments and observations, that exposure to atmospherical air, simply, can neither produce, nor increase inflammation. He discovered in the blood so many phenomena, connected with life, and not to be referred to any other cause, that he considered it alive in its fluid state. He improved the operation for the fistula lachrymalis by removing a circular piece of the os unguis, instead of breaking it down with the point of a trocar. He explained better than any of his predecessors all the highly interesting modern doctrines, relative to inflammation, union by the first intention, suppuration, ulceration, and mortification. His writings also throw considerable light on the growth, structure, and diseases of the teeth. As instances of his operative skill, it deserves to be mentioned, that he removed a tumour from the side of the head and neck of a patient at St. George's Hospital, as large as the head, to which it was attached; and by bringing the cut edges of the skin together, the whole wound was nearly healed by the first intention. He likewise dissected out of the neck a tumour, which one of the best operators in this country had declared, rather too strongly, that no one, but a fool, or a madman, would meddle with; and the patient got perfectly well. But, perhaps, the greatest improvement which he made in the practice of surgery, was his invention of a new mode of performing the operation for the popliteal aneurism, by taking up the femoral artery on the anterior part of the thigh, without opening the tumour in the ham. (See *Trans. of a Society for the Improvement of Med. and Chir. Knowledge.*) The safety and efficacy of this method of operating have now been fully established, and the plan has been extended to all operations for the cure of this disease in every practicable situation. (See *Aneurism*.)

According to Sir Everard Home, Mr. Hunter was also one of the first, who taught, that cutting out the bitten part was the only sure mode of preventing hydrophobia; and he lengthened the time, in which this proceeding might be reasonably

adopted, beyond the period which had been generally specified.

His researches into the nature of the venereal disease, and his observations on the treatment, will for ever make a lasting monument of his wonderful powers of reasoning and investigation. If he left some points of the subject doubtful and unsettled, he has admirably succeeded in the elucidation of others; and his work on this interesting disorder, is, with all its defects, the best which is yet extant.

Even the language and mode of expression of this great man were his own; for, so original were his sentiments, that they could hardly be delineated by any ordinary arrangement of words. His phrases are still adopted in all the medical schools of this country, and continue to modify the style of almost every professional book: whether with advantage, or not, may be doubtful. Great as Mr. Hunter's merit as a surgeon was, it was still greater as a comparative anatomist and physiologist. His museum and his papers in the *Phil. Trans.* will for ever attest his greatness in these characters.

At the period, when the preceding distinguished men upheld the character of their profession in Great Britain, Lancisi, Morgagni, Molinelli, Bertrandi, Paletta, Guattani, Masgagni, Matani, Troja, and Moscati, were doing the same thing in Italy. Bertrandi's *Treatise on the Operations of Surgery*, and Troja's work on the *Regeneration of Bones*, are even at this day works of the highest repute. The credit of the Italian surgeons is still honourably maintained, by Monteggia, Scarpa, Assalini, Morigi, and others. In Holland flourished Albinus, Deventer, Sandifort, and Camper; and, in Germany, and the north of Europe, the immortal Haller, Heister, well known for his "*Institutiones Chirurgiæ*;" Platner; Roederer (*Elementa Artis Obstetriciæ*. Goett. 1752. *Obs. de Partu Laborioso*. Decad 11. 1756); Stein; Bilguer; Acrell; Callisen; (*Principia Systematis, Chirurgiæ Hodiernæ*, 2 vol. 8vo.); Brambilla; Theden (*Progrès ultérieurs de la Chirurgie*); Schmucker, (*Vermischte Chirurgische Schriften*, B. 3. and *Chir. Wahrnehmungen*); Richter; (*Traite des Hernies*, 2 vol. in 8vo. *Bibliothèque de Chirurgie*; *Anfangsgr. der Wundarzneykunst*. 7 vol. and *Obs. Chirurgicarum Fasc.*) Also Arnemann, Weidmann, Beer, Soemmering, Creutzenfeldt, Hesselbach, Hufeland, &c. should not be forgotten, several of whom are still pursuing their useful and honourable career.

On the continent, the Academy of Surgery at Paris was long considered quite as the solar light of this branch of science. The French Revolution, which, by a fatal abuse, involved in the same prohibition, both useful and pernicious societies, did not spare even this beneficial establishment.

Although the Academy was deprived of the talents of M. Louis, who died a short time before its suppression, it yet had at this period several members, worthy of continuing its labours and supporting its reputation; Sabatier, Desault, who may be regarded as the Pott of France, Chopart, Lassus, Peyrilhe, Dubois, Percy, Baudelogue, Pelletan, Sue, &c.

Desault wrote:

1. *Journal de Chirurgie*; 4 vol. 8vo.

2. *Œuvres Chirurgicales, recueillies par Bichat*, 3 vols. 8vo.

Chopart:

1. *Traite des Maladies des Voies Urinaires*, 2 vols. in 8vo.

Percy:

1. *Pyrotechnie Chirurgicale*, &c.

Baudelogue:

1. *Traite des Accouchemens*, 2 vols. in 8vo.

The Academy of Surgery in France was succeeded by what is named the *Ecole de Médecine*. Desault, who was almost a stranger in the former, became quite the leading character in the latter. Several things recommended him strongly to the remembrance and admiration of posterity; the exactness and method, which he introduced into the study of anatomy: the ingenious apparatuses which he invented for the treatment of fractures: a noble ardour in his profession, which he knew how to impart to all his pupils: his clinical lectures upon surgery, which were the first ever delivered: and the boldness and simplicity of his modes of operating. Indeed, such was his genius, that even when he practised only methods already understood, he did them with so much adroitness, that he rather appeared to be the inventor of them. From the *Ecole de Médecine* have issued Boyer, Richerand, Dubois, Lheritier, Manoury, Lallemant, Petit de Lyon, Bichat, &c.

The researches of Bichat, who quitted surgery, powerfully contributed to the advancement of physiological science. His mind, richly stored with the positive facts which he had learned in the study of surgery, conceived no less a project, than that of rebuilding the whole edifice of medicine. Some courses of lectures upon the *materia medica*, internal clinical medicine, and morbid anatomy, announced this vast design, which was frustrated by a premature death. Bichat, as a physiologist, and man of very original genius, may be considered as the John Hunter of France; but his qualities were of a different cast, and hardly admit of comparison with those of Hunter, whose investigations were not limited to man, but extended to the whole chain of animated beings. Bichat died in the midst of his labours, and in dying his greatest regret was that of not having completed them. His example, says Richerand, proves most convincingly what

Boerhaave always inculcated, how indispensable the study and even the practice of surgery are to him, who would wish to be a distinguished and successful physician. (*Nosogr. Chir. Tom. 1, p. 25.*)

Perhaps, nothing contributed so materially to the improvement of surgical knowledge, as the establishment of the Royal Academy of Surgery in France; a noble institution, which, for a long while, gave our neighbours infinite advantage over us, in the cultivation of this most useful profession. Indeed, every one, truly interested in the improvement of surgery, cannot fail to regret the discontinuance of a society, in which emulation and talents were so long united for the benefit of mankind. The various dissertations, published by the illustrious members of the academy, will serve as a perpetual memorial of the spirit, ability, and success, with which the objects of the institution were pursued; and centuries hence, practitioners will reap from the pages of its memoirs the most valuable kind of surgical information. Unfortunately, this establishment, which was overthrown by the agitation of the French Revolution, has had only a very inferior substitute in the *Ecole de Médecine*.

Were I to name any one thing, which, in my opinion, would have the greatest influence in giving life to the study and cultivation of surgery in this country, I should without hesitation assign such importance to the establishment of an institution in the metropolis, on the same grand, liberal, and encouraged plan, as the late Royal Academy of Surgery in France.

At the same time, I am conscious, that the present Medical and Chirurgical Society of London have every claim to the encouragement and gratitude of the profession. No other institution of the kind has ever done so much in so short space of time. Many of the facts, which they have collected and published, are of considerable importance, especially those relating to the subjects of aneurism and hemorrhage. Their library is already the most select, valuable, and complete, collection of medical literature in Great Britain; and it is daily receiving additions both by large purchases at home and abroad, and by the liberal donations of its members. The intercourse and correspondence, which such a society continually maintain amongst the innumerable scattered members of the profession, cannot fail to be attended with the most beneficial consequences. A generous and useful sort of emulation is thus kept alive; the spirit of enquiry is prevented from slumbering; and every individual who ascertains a new fact, has now the means of making it known to the world, with all the expedition, which its importance may demand.

Within the last twenty, or thirty years,

most important improvements have certainly been made in almost every branch of surgery; and it must gratify every Englishman to find, that his own countrymen have acted a very leading part in effecting an object, in which the interests of mankind are so deeply concerned.

Before the time of Mr. John Hunter, our ideas of the venereal disease were surrounded with absurdities; and it is to this luminary that we are in an eminent degree indebted for the increased discrimination and reason, which now prevail, both in the doctrines and treatment of the complaint. It must be confessed, however, that much yet remains to be made out, respecting the nature and treatment of syphilitic disorders. Need I mention a greater proof of the truth of this remark, than the sudden change of practice recently introduced into some of the principal hospitals in London, mercury being now not exhibited in more than one out of ten cases, for which this medicine a few years ago was always deemed indispensable? Numerous cases, having all the characters of primary venereal sores, seem now to be curable by simple dressings and cleanliness. In short, so different is every thing from what it used to be, that one is almost tempted to suppose the nature of the venereal disease totally altered. Some observations on this important topic are offered in another place. See *Venereal Disease*.

Strictures in the urethra, an equally common and distressing disease, were not well treated of before Mr. Hunter published on the venereal disease; and the advantage of armed bougies in the treatment of certain cases has been subsequently pointed out by Sir Everard Home.

Ruptures, those common afflictions in every country, have received in modern times, highly interesting elucidations from the labours of Pott, Camper, Richter, A. Cooper, Hey, Gimbernat, Hesselbach, Scarpa, Lawrence, &c.

The treatment of injuries of the head has been materially improved by Quesnay, Le Dran, Pott, Hill, Desault, and Abernethy.

The disease of the vertebra, which occasions paralysis of the limbs, formerly always baffled the practitioner; but, the method, proposed by Mr. Pott, is now frequently productive of considerable relief, and sometimes of a perfect cure.

The mode of treating lumbar abscesses has been rendered much more successful, than formerly, and, for this change, the world is indebted to Mr. Abernethy.

The almost infallible plan of curing hydroceles by an injection, as described by Sir James Earle, may also be enumerated amongst the recent improvements.

The increasing aversion to the employment of the gorget in lithotomy, and the many distinguished advocates for the use of better instruments in this operation,

may be hailed as propitious omens of beneficial changes in this part of practice.

The diseases of the eyes, to which affections English surgeons seemed to pay much less attention, than was bestowed by foreign practitioners, now obtain due attention in this country. Although we have generally had some distinguished oculists, our regular surgeons have generally been wonderfully ignorant of this part of their profession, and uninformed on the subject, they have given up to professed oculists and quacks one of the most lucrative and agreeable branches of practice. However, the able writings of Daviel, Wenzel, and Ware, begin now to be familiarly known to practitioners: and the observations of Scarpa, Richter, Beer, Wardrop, and Saunders, will soon have immense effect in diffusing in the profession a due knowledge of the numerous diseases, to which the organs of vision are liable. As likewise the generality of the hospital surgeons in London have, during the last thirty years, grossly neglected the study of the diseases of the eye, and conscientiously refused to have any thing to do with these cases, the public at length saw the necessity of establishing Eye Infirmarys, where such afflictions might be more attentively observed and relieved. Some of these have now become excellent schools, in which the rising generation of surgeons have abundant opportunities of studying the nature of all the diseases of the eyes, and the most approved methods of treatment.

While, however, I am thus commending separate institutions for disorders of the eye, it becomes me to express my regret for the long continued neglect, and the ignorance of these diseases, manifested by several hospital surgeons, which were in fact the original causes of those distinct establishments. For, according to my conceptions, it would have been far better to have had the practice in eye-cases exhibited in the common great schools of surgery, the large hospitals of London. I am of this opinion, not only because I think these diseases would then have met with more general and public observation; but, also because I have always considered all unnecessary subdivisions of practice, in short all measures which tend to throw particular cases, into the hands of a few individuals, hurtful to the best interests, and degrading to the character of the profession.

In the treatment of aneurismal diseases, English surgeons have much to be proud of. All the boldest operations in this branch of surgery have been devised by the genius, and executed by the spirit and skill of British surgeons. Even M. Roux himself is here obliged to confess our superiority. (*Parallèle de la Chirurgie Angloise*, &c. p. 249.) The carotid artery, the ex-

ternal and internal iliac, and the subclavian, have all been successfully tied by surgeons of this country. The first operation, in which the external iliac was tied, I was a spectator of: it was performed by Mr. Abernethy in Bartholomew's hospital, and it has subsequently been repeated in many examples, both in this country and others, with considerable success. I had the honour of seeing the same gentleman likewise tie the carotid, in the first instance of that operation in England. This important measure has also now been frequently practised with success, and it constitutes one of the great modern improvements in the operative part of surgery.

In the article Aneurism, I could have cited many other examples, in which the carotid artery has been successfully tied; but, the safety and propriety of the operation are now so generally known and acknowledged, that more facts of the same kind appeared superfluous. Indeed, so little are surgeons now afraid of the ill effects upon the brain, that the carotid artery has lately been tied merely for the purpose of enabling the operator to take away a large tumour, including the whole of the parotid gland, from the side of the neck, without risk of hemorrhage. This mode of proceeding was adopted by Mr. Goodlad, surgeon at Bury, in Lancashire. (See *Medico-Chir. Trans.* Vol. 7, p. 112.) Before I quit this subject, my feelings call upon me to express the high opinion which I entertain of Mr. Hodgson's Treatise on the Diseases of Arteries and Veins, published in 1815, a work, which reflects great credit on English surgery, and contains practical precepts far superior to those of the immortal Scarpa.

In the modern practice of surgery, a variety of old prejudices are gradually vanishing. Peruvian bark, not many years ago, was regarded as a sovereign remedy and specific for nearly all cases of gangrene; and in these and many other instances, it was prescribed without any discrimination, and in doses beyond all moderation. But, the false idea, that this medicine has any specific effect in checking mortification, no longer blinds the senses of the most superficial practitioner. He neither believes this doctrine, nor the still more absurd opinion, that strength can be mysteriously extracted from this vegetable substance, and communicated to the human constitution, in proportion to the quantity, which can be made to remain in the stomach. This subject, however, we have duly discussed in the articles *Cinchona* and *Mortification*.

The removal of this deeply rooted prejudice, concerning the virtues of bark, in stopping mortification, will pave the way to better and more successful practice.

But, upon the subject of mortification the present day opens to us the investigation of a point, which is of the first-rate

consequence. Every surgeon is aware, that when a limb is affected with mortification, amputation is absolutely necessary to effect a cure. This is generally acknowledged; but, the performance of the operation has since the time of Mr. Pott, only been sanctioned when the mortification has manifestly ceased to spread, and a line of separation is formed between the dead and living parts. All other instances, in which the disorder was in a spreading state, were left to their fate. It is true, some of the old surgeons occasionally ventured to deviate from this precept; but, as they did so, without any discrimination, or knowledge of the particular examples, which ought to form an exception to the general rule, their ill success cannot constitute a just argument against the plan of amputating earlier in a certain description of cases.

Now, if modern experience can prove, that many lives may be saved by a timely performance of amputation, under circumstances, in which it has until lately been generally condemned, we must allow, that the established innovation will be one of the greatest improvements in the practice of the present time.

For reviving the consideration of this question, and venturing to deviate from the beaten path, the world is much indebted to that eminent military surgeon, M. Larrey. How different his doctrines and practice are from those usually taught in the schools, the article *Mortification* will sufficiently prove.

In the treatment of ununited fractures, the simple and ingenious practice, proposed by Dr. Physic of Philadelphia, merits particular notice, not only on account of the several successful trials, which have been made of it in this country and France; (See *Medico-Chir. Trans.* Vols. 5 & 7, and *Boyer's Traité des Maladies Chir.*) but also because it is perhaps the first improvement that has hitherto been made in the practice of surgery by our transatlantic brethren.

The inestimable treatise of Dr. Jones on Hemorrhage has now produced quite a revolution in all the principles, by which the surgeon is guided in the employment of the ligature for the stoppage of bleeding and the cure of aneurisms. Instead of thick clumsy cords, small firm silks, or threads, are now generally used; and so far is the practitioner from being fearful of tying arteries too tightly, lest the ligature cut through them, that it is now a particular object with him to apply the silk, or thread, with a certain degree of force, in order that the inner coat of the vessel may be divided. If this be not done, the effusion of coagulating lymph, within the artery, an important part of the process of obliteration, cannot be expected as a matter of certainty, and secondary hemorrhage is more likely to occur. But,

In order to convey an adequate idea of the beneficial changes, which Dr. Jones's observations are tending to produce in practice, we have been careful in the article, *Hæmorrhage*, to give a tolerably full account of the results of all his interesting experiments.

Besides using very small, firm, round threads, instead of large, flat tapes, or cords, as was the custom, a few years ago, modern surgeons begin to suspect, that much benefit may also arise from cutting off both portions of the ligature close to the knot, after amputations, the removal of the breast, &c. No one has insisted so much as Mr. Lawrence upon the propriety of examining further the merits of this innovation. If no bad effects result from leaving so small a particle of extraneous substance in the flesh, as the little bit of silk composing the knot and noose on the artery, the practice will form a considerable improvement. The wound may then be brought together at every point; the quantity of extraneous matter in the wound will be lessened to almost nothing; the danger of convulsive affections will be lessened in proportion as a serious cause of pain and irritation is diminished; and the chance of accomplishing perfect union by the first intention will be materially increased. Mr. Lawrence has tried the plan in many instances, and hitherto his experience has not found any ill consequences follow, while it has proved, that many advantages are undoubtedly the result of it. I lately saw this gentleman follow this plan after an operation for femoral aneurism, and he mentioned to me some time ago a case, in which after an operation for popliteal aneurism done by a friend of his in the country, the ends of the ligature were cut off, and the wound united by the first intention. In amputations, the method has been practised by several of our military surgeons; and, although they have probably not employed exactly such ligatures as this mode absolutely requires, the greater part of them have met with hardly any instances of future trouble from the bits of ligature enclosed in the wound. However, if large ligatures be used, the practice is not fairly tried, or rather the practice is not tried at all; because the great principle, on which it answers, is the very small atom of silk composing the extraneous substance, left in the wound, when such ligatures as Mr. Lawrence recommends, are left in the wound. M. Delpech, of Montpellier, and M. Roux of Paris, have also sometimes adopted the new plan of removing the ends of the ligature close to the knot. (See *Parallèle de la Chir. Anglaise avec la Chir. Française*, p. 131.) See *Hæmorrhage* and *Ligature*.

Amongst other real improvements in

modern practice, we must not forget the present more rational method of dressing the wound, after the majority of capital operations, with light, cooling applications, instead of laying on the part a farrago of irritating pledgets and plasters, and a cumbersome mass of lint, tow, flannel and other bandages, woollen caps, &c. The fewer the adhesive strips are the better, if they only hold the lips of the wound together. This is all they are intended to do. Whereas, if you apply more than are necessary for this purpose, they do harm by heating the part, and covering the wound so entirely as to prevent the issue of the discharge. Over the adhesive plasters, let the surgeon be content with placing a simple pledget of spermaceti cerate, and some linen wet with cold water, which will often avert hurtful degrees of pain, and inflammation, by keeping the parts cool.

Wars, which are unfavourable to most other sciences, are rather conducive to advances in surgery. The many new and interesting observations, which M. Larrey has made in the course of his long and extensive military experience, are a proof of what we have been remarking. Pitard, almost the founder of surgery in France, was a military surgeon: Ambroise Paré and Wiseman also collected their most valuable knowledge principally in the service of the army. Mr. Hunter himself gained much of his practical information in the same line of life. To M. Larrey we are indebted for many highly important observations, relating to amputation in cases of gunshot-wounds. In particular, he has adduced a larger and more convincing body of evidence, than was ever before collected, to prove, that, in gunshot injuries, the operation of amputation should always be performed without the least delay, in every instance, in which such operation is judged to be unavoidable, and the ultimate preservation of the limb either impossible, or beyond the scope of all rational probability. He has established the truth of this most important precept in military surgery by innumerable facts, drawn chiefly from his own ample experience, and partly from the practice of many able colleagues. The great operations of the shoulder-joint, and hip-joint amputations, he has executed with success. The necessity for the former, however, he proves may sometimes be superseded, and the limb be saved, by making a suitable incision for the extraction of the splintered portions of the upper part of the humerus. This method, which was in many instances done with success in the peninsular war, was, we believe, originally proposed and practised by M. Boucher. (See *Mem. de l'Acad. de Chir. Tom. 2, 4to.*) It was, however, more particularly described and even

practised by Mr. C. White, of Manchester. (See his *Cases in Surgery*.) Lately, it has been repeated with success by Mr. Morell in the York Hospital. (See *Medico-Chir. Trans. Vol. 7.*) See *Amputation*.

Amputation at the hip-joint, performed only in the most dreadful cases, because itself the most dreadful operation in surgery, M. Larrey has performed five times, and twice, (we believe) with success. This proceeding has also been adopted by Mr. Brownrigg, staff surgeon, and Mr. Guthrie, Deputy Inspector of Military Hospitals, who in this way effected two recoveries. All these gentlemen, however, have had failures, and their successful attempts bear only a small proportion to the large number of deaths, known to have followed amputation at the hip in the many cases, in which it has now been undertaken. We have no doubt, on the whole, that examples do occur, in which this severe operation is the only means, affording a chance of life; but, we deem the chance so small, that, it is to be hoped, no surgeons will perform it, except under the authority of the united opinion of a board, or consultation, of the best informed practitioners, whom circumstances will allow to assemble. See *Amputation*.

In military surgery, the useful innovation of *ambulances*, or light caravans, furnished with a proper number of surgeons assistants and orderlies, and capable of keeping up with the van-guard, if requisite, is undoubtedly the best means of affording speedy surgical assistance to the wounded on the field of battle, and ought to be enumerated as one of the greatest modern improvements.

The French surgeons-general, Barons Percy and Larrey, deserve the chief praise for their successful exertions in organizing and bringing to perfection so indispensable an establishment. Although we have hitherto had no arrangement of this kind in our armies, and it is not likely to be made in the present time of peace and economy, I have not the slightest doubt of its taking place at some future period. I also feel authorized in stating, that the want of a small corps of men, trained for the assistance of the medical staff officers, both in the field and general hospitals, was what was seriously felt in the late campaigns in the Netherlands and France. The account of the subject well deserves perusal; and it may be seen either in *Larrey's Mémoires de Chirurgie Militaire*, or in the *Dict. des Sciences Médicales*, Tom. 5.

SUSPENSORY. A bandage for supporting the scrotum; a bag-truss. Bandages of this kind are now usually sold at the shops, and seldom made by surgeons themselves; therefore, a particular description of them is not essential in

this work. In cases of *hernia humoralis*, *varicocele*, *cirsocele*, some particular ruptures, and several other affections of the testicle, and spermatic chord, a suspensory bandage is of infinite service.

SUTURES. (from *suo*, to sew.) A suture, in surgery, means a mode of uniting the edges of a wound, by keeping them in contact with stitches.

Mr. Sharp remarks, that "when a wound is recent, and the parts of it are divided by a sharp instrument, without any further violence, and, in such manner, that they may be made to approach each other, by being returned with the hands, they will, if held in close contact for some time, reunite by inosculation, and cement, like one branch of a tree ingrafted on another. To maintain them in this situation, several sorts of sutures have been invented, and formerly practised, but the number of them has, of late, been very much reduced. Those now chiefly described are the *interrupted*, the *glover's*, the *quilled*, the *twisted*, and the *dry*, sutures; but, the interrupted and twisted are almost the only useful ones, for the quilled suture is never preferable to the interrupted; the dry suture is ridiculous in terms, since it is only a piece of plaster, applied in many different ways, to reunite the lips of a wound; and the *glover's*, or uninterrupted stitch, which is recommended in superficial wounds, to prevent the deformity of a scar, does rather, by the frequency of the stitches, occasion it, and is therefore to be rejected, in favour of a compress and sticking plaster." (*Oper. of Surgery*.) The twisted suture is described in speaking of the *hare-lip*; and *gastrostomy*, which also properly belongs to the present subject, forms a distinct article in this Dictionary.

INTERRUPTED SUTURE.

The wound being cleansed from all clots of blood, and its lips being brought evenly into contact, the needle, armed with a ligature, is to be carefully carried from without, inwards to the bottom, and so on from within outwards. Care must be taken to make the puncture far enough from the edge of the wound, lest the ligature should tear quite through the skin and flesh. This distance, according to Mr. Sharp, may be three, or four-tenths of an inch. The other stitches required are only repetitions of the same process. The threads having been all passed, you are in general to begin tying them in the middle of the wound; though, if the lips be held carefully together, (says Mr. Sharp,) it will not be of great consequence, which stitch is tied first. (See *Operations of Surgery*, Chap. 1.)

Surgical writers in general state, that

the number of stitches must, in a great measure, depend upon the extent of the wound. The common rule is, that one suture is sufficient for every inch of the wound; but, that, in some instances, a stitch must be more frequently made, particularly when a wound gapes very much, in consequence of a transverse division of muscles. As we have already explained, it is necessary to pierce the skin, at a sufficient distance from the sides of the wound, lest the thread should cut through the flesh in a short time: but, though Mr. Sharp lays down the necessary distance, in general, as three, or four-tenths of an inch, and others advise the needle to be always carried through the deepest part of the wound, we must receive these directions, particularly the last, as subject to numerous exceptions. When a wound is very deep, it would be conspicuously absurd, and even, in many instances, dangerous, to drive the needle through a vast thickness of parts. Other wounds, of considerable length, might not be, in some places, four-tenths of an inch deep; though it is true, sutures could never be requisite at such points.

The needles for making the interrupted suture will pass, with the greatest facility, when their shape corresponds exactly with the segment of a circle, and they should always form a track of sufficient size to allow the ligatures, which they draw after them, to pass through the flesh with the utmost ease.

The interrupted suture obviously receives its name from the interspaces between the stitches; and it is the one most frequently employed. Its action is always to be assisted, and supported, either with the uniting bandage, (see *Bandage*,) or with strips of adhesive plaster, compresses, &c.

QUILLED SUTURE.

As Mr. John Bell has observed: "when the wound was deep among the muscular flesh, the old surgeons imagined, that so large a wound could not be commanded by the common interrupted suture, however deep the stitches might be driven among the flesh; they were, besides, fearful of using the continued (glover's) suture in deep gashes, lest the wound should be made to adhere superficially, while it was still open within, forming perhaps a suppuration, or deep collection of matter. They believed, that a deep muscular wound could not be safely healed, without a degree of suppuration; while they wished to bring it together at the bottom, they were afraid to close it very exactly at the mouth, lest the matter should be collected in the deeper parts of the wound; it was, for this purpose (says Mr. John Bell) that they used, what they called the com-

pound, or quilled suture. It is merely the interrupted suture, with this difference, that the ligatures are not tied over the face of the wound, but over two quills, or rolls of plaster, or bougies, which are laid along the sides of the wound. In performing this suture, we make first two, three, or four stitches, of the interrupted suture very deep, and then, all the ligatures being put in, we lay two bougies along the sides of the wound, then slip one bougie into the loop of the ligatures on one side, drawing all the ligatures from the other side, (Mr. Bell should rather have said towards the other side,) till that bougie is firmly braced down. Next we lay the other bougie, and make the knots of each ligature over it, and draw it also pretty firm; and thus the ligatures, in form of an arch, go deep into the bottom of the wound, and hold it close, while the bougies, or quills, keep the middle of the wound, and lips of it pressed together with moderate closeness, and prevent any strain upon the threads, or any coarse and painful tying across the face of the wound." In a note Mr. J. Bell says, that Dionis violently reprobates the quilled suture; but, that De la Faye (the annotator on Dionis) says, it is good for deep muscular wounds. The quilled suture is now scarcely ever employed; nor has it any advantages, except, perhaps, in some wounds of the belly. (See *Principles of Surgery*, Vol. 1, p. 50.)

I think the reader will more easily comprehend the manner of making the quilled suture, by directing it to be done as follows: Take as many needles, as stitches intended to be made; arm them with a double ligature, or one capable of being readily split into two; introduce the ligatures through the wound; cut off the needles; lay a piece of bougie along one side of the wound, and tie the ends of the ligatures over it. Next draw the other extremities of the ligatures, so as to bring the first piece of bougie into close contact with the flesh; lay the second piece of bougie along the opposite side of the wound, and tie the other ends of the ligatures over it, with sufficient tightness.

GLOVER'S SUTURE.

This had also the name of the continued suture. It was executed by introducing the needle first into one lip of the wound, from within outwards, then into the other in the same way; and, in this manner the whole track of the wound was sewed up.

The glover's suture has long been rejected by all good surgeons, as improper to be employed in cases of common wounds. It was not, however, till very lately, that this suture was totally aban-

done; for, Mr. Sharp, and several eminent writers, since his time, have advised its adoption in wounds of the stomach and intestines. From what we have said in the articles *Wounds of the Abdomen*, and *Hernia*, the reader will perceive, that even in such particular instances, the glover's suture would not be advisable; so that it may in every point of view, be now considered as totally disused in every case of surgery, which can possibly present itself. When we remember, in making this suture, how many stitches are unavoidable; how unevenly, and in what a puckered state, the suture drags the edges of the skin together; and what irritation it must produce; we can no longer be surprised, at its now being never practised on the living subject. It is commonly employed for sewing up dead bodies; a purpose for which it is well fitted; but, for the honour of surgery, and the sake of mankind, it is to be hoped, that it will never again be adopted in practice.

FALSE OR DRY SUTURE.

This term signifies the retaining of the edges of wounds in contact, by means of sticking plaster, in various manners, and the expression, as Mr. Sharp has justly remarked, is highly ridiculous, as no kind of sewing is concerned with the method. The proper plan of dressing wounds with adhesive plaster, is detailed in describing the treatment of incised wounds. (See *Wounds*.) Besides the common way of using strips of sticking plaster, some surgeons have been partial to little particularities. M. Petit used adhesive plasters, which had in the middle, one, or two holes, or even more according to the extent of the wound. Such openings enabled the surgeon not only to see, whether the edges of the wound were in accurate contact, but also in what state they were; and the apertures afforded an opportunity for applying to the wound such remedies, as were deemed expedient. However, as when common strips of adhesive plaster are properly applied, there should generally be left a certain uncovered interspace, between every two, Petit's plan had no particular advantage in this respect.

Another method was to take two pieces of adhesive plaster, of a breadth and length proportioned to the extent and depth of the wound. Three, or four ligatures, or tapes, were then fastened to one of the edges of each piece of plaster. Both pieces were then warmed, and put on the skin, along the sides of the wound. Then the edges of the cut were evenly brought into contact, and held so by an assistant, until the surgeons confined them permanently in this position, by tying each two

corresponding ligatures, or tapes. A pledget was next applied over the wound, and a longitudinal compress over each plaster. Over these, a large square compress was put, and the whole of the dressings were covered, and supported with a bandage. The following day, it was usual to inspect the wound, and if the ligatures seemed lax, they were tightened; but, if in a proper condition, they were not meddled with. Sometimes, when much inflammation and swelling had come on, the ligatures were loosened; and, when these symptoms had abated, the ligatures were tightened again, if necessary.

REMARKS ON THE EMPLOYMENT OF SUTURES.

Sutures, by which I mean such as were made with a needle and ligature, were much more frequently employed by the old surgeons, than they are by the moderns. All the best practitioners of the present day, never resort to this method of holding the sides of a wound in contact, except in cases, in which there is a real necessity for it, and other modes will not suffice.

There were, indeed, certain instances, in which the employment of sutures was long ago forbidden. Of this kind were envenomed wounds, in which accidents, the destruction of the poison always formed a principal indication in the treatment.—Wounds, accompanied with considerable inflammation, were not deemed proper for the use of sutures, as the stitches had a tendency to increase the inflammatory symptoms. Also, as contused wounds necessarily suppurated, and, consequently, could not be united, sutures were not recommended for them; nor were they judged expedient for wounds, attended with such a loss of substance, as prevented their lips from being placed in apposition. Wounds, penetrating the chest, were not united by sutures; nor were those, in which large blood-vessels were injured; at least, until all danger of hemorrhage was removed by such vessels being tied.

Dionis believed, with several other authors, that wounds should not be united, when bones were exposed, on account of the exfoliations, which might be expected. This precept is no longer valid; for, when bones are neither altered, nor diseased, and are only simply denuded, or divided with a cutting instrument, no exfoliations will commonly follow, if the surgeon take care to replace the fresh cut soft parts, so as to cover the exposed portion of the bone. The practicableness of uniting wounds, attended with the division of a bone, is confirmed, by numerous facts. M. de la Peyronie communicated to

the Academy of Surgery, in France, a case, which is very conclusive on this point. A man was wounded with a cutting instrument, in an oblique direction, on the external and middle part of the arm. The bone was completely cut through, together with the integuments and muscles; in such a manner, that the arm only hung by an undivided portion of the skin, about an inch wide, under which were the large vessels. M. de la Peyronie tried to unite the parts, being convinced, that it would be time enough to amputate afterwards if the case should require it. He placed the two extremities of the divided bone in their natural situation; made several sutures for promoting the union of the soft parts; and applied a bandage to the fracture. In this bandage, there were slits, or apertures, over the wound, to allow the dressings to be applied. Spirit of wine, containing a little muriate of ammonia, was used as a topical application, and the fore-arm, and hand, which were cold, livid, and insensible, were also fomented with the same. By these means, the natural warmth was restored, and the wound was dressed. In a week, the dressings were removed, through the opening in the bandage; in a fortnight, they were changed, a second time, and the wound seemed disposed to heal. On the eighteenth day, the healing had made progress; the part had a natural appearance; and the beating of the pulse was very perceptible. M. de la Peyronie now substituted a common roller, for the preceding kind of bandage. Care was taken to change the dressings, every ten days. In about seven weeks, all applications were left off, and, at the end of two months, the patient was quite well, with the exception of a little numbness in the part. This case is one of the most important in all the records of surgery; for, it displays, in a most striking manner, what very bad wounds it is the duty of the surgeon to attempt to unite; and, above all, it shews the propriety of attempting to save many compound fractures, which, judged of only from first appearances, would lead almost any one to resort to amputation. When the divided parts, in such cases, have been put into contact, the appearances are quite altered.

From what has been already stated, it appears, that surgeons, a considerable time back, did not at once sew up every sort of wound. The best modern practitioners employ sutures much less frequently, than their predecessors. M. Pibrac's dissertation on the abuse of sutures, inserted in the third volume of the *Memoirs of the Academy of Surgery*, has had considerable effect in producing this change, and I may safely add, this im-

provement in practice. This judicious and enlightened practitioner opposed the method of uniting wounds by means of sutures, which, he contended, ought never to be adopted in practice, except in certain cases, in which it was absolutely impossible to keep the sides of the wound in contact, by the adoption of a proper posture, and the aid of a methodical bandage. Such circumstances M. Pibrac represents, as exceedingly rare, if they can occur at all. He speaks of sutures, as very seldom fulfilling the intention of the surgeon, who, in the majority of cases, in which he employs them, finds himself necessitated to remove them, before they have accomplished the wished-for end. M. Pibrac believes, that sutures are generally more hurtful, than conducive to the union of wounds; and that when they succeed, they do not effect a cure more speedily, than a proper bandage. He cites numerous cases of very extensive wounds of the abdomen, neck, &c. for the cure of which a bandage proved effectual, and this even in many instances, in which sutures had previously failed, and cut their way through the flesh. M. Louis adopted the opinions of M. Pibrac, and published, in the fourth volume of *Mem. de l'Acad. de Chirurgie*, a dissertation, in which he endeavours to shew, that the hare-lip can be better united, by means of the uniting bandage, than when sutures are used for the purpose.

As far as I can judge, the fair statement of the matter is, that sutures are by no means requisite in the generality of wounds; but, that there are particular cases, in which, either their greater convenience, or superior efficacy, still makes them approved, and employed, by all the most eminent practitioners of the present day. Since sutures cannot be practised, without making additional wounds, and occasioning pain, and since the ligatures always act as extraneous bodies in the parts, in which they are introduced, exciting more or less inflammation, and suppuration round them; there can be no doubt, that their employment is invariably wrong, whenever the sides of a wound can be maintained in contact by means less irritating. For, what is it which generally counteracts the wishes of the surgeon in such cases, and makes his attempts, to make the opposite surface of wounds grow together, prove unavailing? Is not the general cause too high a degree of inflammation, which necessarily ends in suppuration? Are not sutures means exceedingly likely to augment inflammation, both by the additional wounds of the needles, and the still more pernicious irritation of the threads, which always act as foreign bodies, sometimes producing not merely an increase of in-

flammation, and suppuration in their track; but, frequently, such ulceration as enables them to cut their way out, or else sloughing of the parts; or, in particular constitutions, a very extensive erysipelatous redness round the wound.

By the ulcerative process, just mentioned, sutures very often cease to have the power of any longer keeping the edges of wounds in contact; as the observations of M. Pibrac, and, indeed, what every man may daily remark in practice, fully testify. The violent inflammatory symptoms, which they excite, frequently oblige the surgeon to cut them, and withdraw them altogether.

But even admitting, that, by the general adoption of sutures, some wounds would be united, which could not be so, were this means of accomplishing an union (generally speaking) abandoned, still it must be allowed, on the other hand, that the cause of some wounds not uniting, is entirely ascribable to the irritation, occasioned by the sutures themselves. Hence, if it be only computed, that as many wounds are prevented from uniting by the irritation of sutures, as other wounds, which are united by their means, and could be united by no other methods, we must still perceive, that mankind would be no sufferers, and surgery undergo no deterioration, were sutures altogether rejected from practice. I believe, however, that every man, who has had opportunities of observation, and has made use of them, with an unprejudiced mind, will feel persuaded, that more wounds are hindered from uniting by sutures, than such as are healed by them, and, *could not be united by other means.*

But, prudent practitioners are not obliged, either to condemn or praise, the use of sutures, in every instance, without exception. Men of independent principles will always adopt the line of conduct, which truth points out to them as that which is right; nor will they obstinately side with M. Pibrac and M. Louis, in contending that sutures are always improper and disadvantageous, nor, with other bigoted persons, who may use sutures in every kind of wound whatever.

Sutures are, perhaps, still rather too much employed, and in all probability, will long be so. It will be difficult entirely to eradicate the prejudices, on which their too frequent use is founded, as long as we see, what may be called, the *Mâîtres de l'Art*, holding up the practice for imitation, in every principal hospital in the kingdom. Such surgeons, however, as are ready to imbibe fair and candid sentiments on the subject, and to qualify themselves for practising this part of surgery, with judgment, should by no means neglect to read, both what M. Pibrac and M. Louis,

have written on the subject. I know, that the latter authors are a little too sanguine, in their representations; but, as I have already remarked, sutures are still rather too much used, and something is yet necessary to do away a certain unwarranted habit of having recourse to them in several particular cases. Nothing will tend to produce this desirable change so much, as the perusal of every argument against their employment.

I am decidedly of opinion, not from what I have read, but what I have actually seen, that the sides of the generality of wounds are capable of being effectually kept in contact, by means of a proper position of the part, the aid of strips of adhesive plaster, and that of compresses, and bandages. I believe, that such success can be obtained, with every advantage, which can be urged in favour of sutures, and without their disadvantages; such as greater pain, inflammation, &c. I even think, with M. Louis, that the hare-lip could in general be united very well, by means of a bandage; but, still, I am of opinion, that the twisted suture is attended with least trouble, is most suited for universal practice, and, that, unless such pains were taken, as many practitioners would not, and others could never take, the method by bandage would frequently fail.

I find it exceedingly difficult to lay down any fixed principles for the guidance of the surgeon, in respect to when he ought, and when he ought not to use sutures.

Perhaps, sutures should be made use of, for all cuts and wounds, which occur in parts, which are subject to an unusual degree of motion, such as would be apt to derange the operation of bandages, sticking plaster, and compresses. Hence, the propriety of using the twisted suture for the hare-lip.

Sutures are probably, for the most part, advantageous, in all wounds of the abdomen, of a certain length and attended with hazard of the viscera making a protrusion. In this situation, the continual motion and action of the abdominal muscles, in carrying on respiration, besides the tendency of the viscera to protrude, may be a reason in favour of the use of sutures.

When two fresh-cut surfaces positively cannot be brought into contact, by sticking plaster, bandages, the observance of a proper posture, &c. there can be no doubt of the advantage of using sutures, if they will answer the purpose. Some wounds of the trachea; some wounds made for the cure of certain fistulous communications between the vagina and bladder; or others for the cure of similar affections in the perinæum; afford instances of cases, to which I allude.

I observe, that many of the best operators in this metropolis, use sutures for bringing the sides of the wound together after several operations; such as that of removing a diseased breast; castration; and operations for strangulated hernia.

The reason for using sutures in the scrotum, I suppose, arises from the difficulty of keeping the edges of the wound in contact, owing to the great quantity, and looseness of the part. I cannot pretend to determine, whether, in this case, sutures are really necessary, or not: but, after the amputation of the breast, I have no hesitation, in pronouncing their employment wrong and injudicious.

I shall conclude with referring to what M. Pibrac and M. Louis have written on the above subjects, in *Mem. de l'Acad. de Chir.* tom. 3 & 4. Sharp, Dionis, Gooch, Le

Dran, Bertrandi, Sabatier, B. Bell, and J. Bell, have all treated of sutures.

SYMPATHETIC BUBO. (See *Bubo*.)

SYNCHYSIS. (from *συνχυσω*, to confound.) According to Saint-Yves, and Maître-Jan, a kind of suppuration in the situation of the vitreous and crystalline humours. The term *synchysis* now more commonly denotes the confusion of the humours of the eye, occasioned by blows, and attended with a rupture of the internal membranes, and capsules. (See *Encyclopédie Méthodique*; Part. Chir. Art. *Synchyse*.)

SYNTHESIS. (from *συν*, together, and *θεσις*, position, situation.) A generic term, formerly much used in the schools of surgery, and comprehending every operation, by which parts, which had been divided, were reunited.

SYPHILIS. Lues Venerea. The venereal disease. (See *Venereal Disease*.)

T.

T BANDAGE. A bandage, so named from its figure. It is principally used for supporting the dressings after the operation for the fistula in ano, in diseases of the perinæum, and those of the groins, anus, &c. It is composed of two longitudinal pieces of cloth, of greater, or lesser breadth, according as occasion requires. The transverse piece of cloth serves to go round the body above the hips; the perpendicular piece is sewed, at one of its ends, to the middle of the latter; and, in general, its other extremity is slit into two portions, or tails, about six, or eight inches long. The perpendicular piece of the T bandage applies itself between the glutæi muscles, and to the perinæum; while its two ends, just described, are to be carried between the thighs, and the pudenda, to the right and left, and fastened to the transverse piece, surrounding the body. Besides the common T bandage, there is another one named *double*, which has two perpendicular pieces, sewed to the transverse one, about four inches apart. The double T bandage is said to be more particularly applicable after lithotomy, and for the diseases of the perinæum; because, one may make the two perpendicular pieces cross each other on the part affected, and leave the anus uncovered; an advantage, which the simple T bandage certainly has not. The T bandage may be used in some other ways, as we have noticed, in making mention of it in the article *Bandage*.

TALPA. (a mole.) A tumour, which creeps under the skin, as a mole under the surface of the ground. Such is the etymology. It is often applied to an encysted tumour, which forms on the head, and

contains a paplike matter. (See *Atheroma* and *Tumours, Encysted*.)

TAPPING. See *Paracentesis*.

TARAXIS. (from *ταρασσω*, to disturb.) A slight ophthalmy, or inflammation, of the eye.

TAXIS. (from *τασσω*, to put in order.) The operation of reducing a hernia, with the hand. (See *Hernia*.)

TENDO ACHILLIS. See *Achilles, Tendon of*.

TENT. A roll of lint for dilating openings, sinuses, &c. (See *Spongia præparata*.)

TEREBELLA. (dim. of *terebra*, a perforating instrument.) A trepan, or instrument for sawing out circular portions of the skull. A trephine.

TEREBRA. (from *τρίπτω*, to bore.) A trepan, or trephine. Also an instrument called a perforator, such as is contained in the generality of cases of trephining instruments, and is used for making the hole, in which the centre pin of the trephine is to work.

TESTICLE, DISEASES OF. For an account of many of these affections, I must refer to distinct articles in this Dictionary; for instance, *Cirsocele*, *Fungus Hæmatodes*, *Hernia Humoralis*, *Hæmatocèle*, *Hydrocele*, &c.

Mr. Pott defines *sarcocèle* to be a disease of the body of the testicle, and, as the term implies, it consists in general in such an alteration made in the structure of that organ, as produces a resemblance to a hard, fleshy substance, instead of that fine, soft, vascular texture, which it naturally presents. "*Sarcocèle* (says Callisen) is a name applied to every chronic swelling of the testicle, attended with a total, or partial

conversion of the part into an heterogeneous substance. (*Systema Chirurgiæ Hodiernæ, Pars 2, p. 144.*) According to these definitions, sarcocele becomes a term admitting of almost general application to the morbid affections of the testicle, since most of them are attended with induration, and swelling, of the part. In fact, we find, that the old writers, and a great many of the moderns, call all diseased indurations and enlargements of the testicle, *sarcocele*, whether the disorder be a simple, chronic, indolent tumour, unaccompanied with any symptoms of specific disease, or malignancy, or whether it be a scrophulous, or, what is still more different, and more serious, a truly scirrhus, disorder of the organ. Even the fungus hæmatodes of the testicle was, until lately, often termed sarcocele.

That this vague method of employing the word sarcocele can be attended with no advantage, but, on the contrary, must have a tendency to destroy all useful discrimination, is a proposition, the truth of which is self-evident. I am well aware, that Mr. Pott, and many late writers, set out with an idea, that every sarcocele has a propensity to change into scirrhus, and actual carcinoma, and, therefore, the latter states are considered by these authors only as stages of the same disease. Indeed, it is universally admitted by the best and most experienced observers, that a common indolent sarcocele, a simple fleshy enlargement of the testicle, may change into the peculiar malignant disease, called scirrhus, or cancer. But, yet, it is by no means proved, that all the diseases, which have been comprehended under the name of sarcocele, are accompanied by a risk of their assuming the nature of scirrhus and cancer; for, nothing can be more certain, than that the enlargement of the testicle, produced by fungus hæmatodes, is, from the first to the last, always of one character, and can never change into ordinary scirrhus, or carcinoma. Neither do indolent scrophulous swellings of this organ ever undergo such an alteration, as to deserve the epithets of *scirrhus* and *cancerous*. In opposition to the belief of Mr. Hunter, (see his *Treatise on the Ven. Disease, p. 59,*) some surgeons still imagine, that there is really one kind of chronic enlargement of the testicle, arising from a venereal cause. (*Roux Parallele de la Chirurgie Angloise, &c. p. 305; Richerand, Nosographie Chir. T. 4, p. 300, Edit. 4.*) Now this also has usually been called a sarcocele; it was so named by Pott himself, and if there be such a case, no one will suppose, that it, or any other form of lues venerea, is capable of changing into a true scirrhus, or cancerous disease. Perhaps, therefore, it might be more consistent and advantageous to restrict the appellation of *sarcocele* to an indolent fleshy enlargement of the testicle,

unaccompanied with any present symptoms of malignancy, or any marks of its being the effect of a specific disease; and as soon as the case evinces another character, the name should correspond with the particular nature of the disease.

We need not here enter into a minute account of the various sarcomatous diseases, to which the testicle is subject; for, they have no peculiarity in them, except what depends upon their situation, and the general characters of the different species of sarcoma will be considered in a future article. (See *Tumour.*) The testicle is especially liable to three kinds of sarcoma, which have been named by Mr. Abernethy, the *common vascular*, the *cystic*, and the *medullary*. The latter case, however, which is often called *soft cancer of the testicle*, I shall describe in the present article, in order that the reader may judge, whether there is any material difference between this case, and another distemper to which the testicle is subject. (See *Fungus Hæmatodes.*) Sometimes the testicle is converted into a truly scrophulous mass. It is increased in size, and when cut into, a whitish, or yellowish coagulated matter is discovered, mixed with pus. The complaint is not attended with so much pain, and induration, as a scirrhus disorder of the testicle; nor does it produce any unfavourable state of the health.

As Dr. Baillie observes, the testicle is often found converted into a hard mass, of a brownish colour, and generally intersected with membranes. Sometimes, there are cells in the tumour, which are filled with a sanious fluid. (*Morbid Anatomy, &c. p. 352—353, Edit. 2.*) This is the truly *scirrhus testicle*, which is attended with great hardness, severe pains darting along the spermatic chord to the loins, and an unequal knotty feel. In general the health becomes impaired. To use Mr. Pott's words, sometimes the fury of the disease brooks no restraint; but, making its way through all the membranes, which envelope the testicle, it either produces a large, foul, stinking, phagedenic, ulcer, with hard edges, or it thrusts forth a painful gleet-ing fungus, subject to frequent hemorrhage. (*Pott's Surgical Works, Vol. 2, p. 390, Edit. 1808.*) These latter states of the disease are denominated *cancer of the testicle*.

Sooner, or later, the scirrhus induration extends from the epididymis, upward along the spermatic chord, even within the abdominal ring. In the latter circumstance, the lymphatic glands in the groins usually become diseased; and this extension of mischief, together with the impossibility of removing the whole of the diseased chord, too frequently deprives the patient of every chance of getting well.

I have already stated, that some of the most simple sarcomatous enlargements of the testicle are capable of assuming, in a

very sudden manner, a malignant, and cancerous tendency; and that sometimes the scirrhus induration of the chord makes a rapid progress upward. Hence, that surgeon acts with prudence, who recommends the early extirpation of every testicle, which is incurably diseased, and so deprived of its original organization, as to be totally unfit for the secretion of the semen.

Chronic enlargements of the testicle are sometimes attended with an accumulation of limpid fluid in the tunica vaginalis, and the disease is then termed, *hydrosarcocele*, an appellation first employed by Fabricius ab Aquapendente.

The hardness and swelling of the epididymis, remaining after an acute inflammation of the testicle (see *Hernia Humoralis*), do not constitute a complaint, which surgical authors class with sarcocele; for, the disease hardly ever increases so as to give trouble.

I have stated, that sarcoceles, in common with the generality of other sarcomatous tumours, may change into distempers, which, in point of malignity, and the manner in which they injure the health, are quite as bad as cancer itself. It is said, however, that sarcocele of the epididymis rarely becomes malignant, and is much more easy of cure, than the same disease of the glandular portion of the testicle; but both parts are often diseased together.

Sarcoceles sometimes continue for years, without undergoing any particular change; in other instances, they increase with surprising rapidity. The inconveniences, which they excite, often proceed chiefly from their weight and magnitude: their weight occasions an uneasy, and even a painful sensation in the loins, especially, when the patient neglects to wear a suspensory bandage, or a bag-truss for the support of the part. The danger of a sarcocele arises from the increase and extension of the hardness up the spermatic chord, and from the change of the tumour from its indolent state into a painful, ulcerated, and incurable disease.

A sarcocele sometimes bears a resemblance to hydrocele of the tunica vaginalis. It sometimes has the usual pyramidal shape of the latter disease, and, like it, is always situated at the lower end of the spermatic chord. The chief difference between the two cases seems to be, that the sarcocele is hard, while the hydrocele has a soft, yielding, elastic feel. It should be known, however, that the fungus hæmatodes of the testicle is remarkable for the deceitful feel of fluctuation and elasticity, which it presents; and every surgeon ought to be aware, that a sarcocele is not always particularly hard, and that hydroceles are sometimes exceedingly indurated. The sarcocele, indeed, is not transparent; nei-

ther is the hydrocele in certain instances; and these are cases, in which a mistake may easily be made. Still, with due attention, both diseases may be discriminated with tolerable precision. The sarcocele, when held in the surgeon's hand, seems heavier, than the hydrocele. Every part of a diseased testicle is seldom equally indurated, so that the sarcocele is usually much softer in some places, than others. The hydrocele presents the same kind of feel at every point, except behind, where the testicle is felt. When, in the case of hydrocele, pressure is made in this latter situation, the patient experiences a much more acute sensation, than when the pressure is made upon any other part of the tumour; but, in the example of sarcocele, the patient commonly has the same kind of feel, let the pressure be applied to any part of the swelling whatsoever. When the upper portion of the spermatic chord can be felt, and it seems quite hard and thickened, the surgeon has reason for suspecting the case to be a sarcocele. Lastly, though a hydrocele, when gently handled, may seem very hard, yet, on being more strongly compressed, it will generally betray a soft, elastic feel, which, excepting instances of fungus hæmatodes, is never the case with an indurated sarcocele.

It has been already explained, that a sarcocele is sometimes conjoined with a hydrocele, which case is well known amongst surgeons by the appellation of *hydro-sarcocele*. As the diseased testicle is then surrounded with fluid, it cannot be felt, nor examined by the fingers. However, when an unusual degree of hardness is perceptible at the back part of the tumour, where the testicle is situated, or when the upper portion of the spermatic chord is found to be quite indurated, there is reason for suspecting, that the testicle is diseased. The sarcocele also is commonly the original and principal complaint, the hydrocele not occurring till some time after the enlargement of the testicle.

In some unusual cases, the substance of the scrotum is converted into an indurated mass, which occasionally attains a vast size, and presents the appearance of an enormous sarcocele. An example, in which the tumour weighed 70lb. has been lately published by Dr. Titley. (See *Medico-Chir Trans. Vol. 6, p. 73.*) In one case, recorded by Dr. Cheston, a swelling of this kind was as large as a child's head. On dissection of the parts, the testicle and tunica vaginalis were found to be quite free from disease. The tumour proceeded entirely from an induration of the cellular membrane, which immediately covers the external surface of the vaginal coat. This curious disease is more common in warm climates, and several instances of it were met with in Egypt by M. Larrey. (See *Mém. de Chir.*

Militaire, Tom. 2, p. 110 *et seq.*) Some interesting particulars, relative to it, will be found in another part of this Dictionary. (See *Scrotum*.)

The operation of castration is the most certain means of relieving the patient from sarcocoele. This measure, however, is not invariably practicable, nor is it always necessary; for, sometimes the induration of the testicle admits of being dispersed by the judicious employment of internal medicines and external applications. The hope of accomplishing this desirable object may reasonably be entertained, when the swelling is not very large, when it has not existed a considerable time, and when it is not attended with very great induration. Experience has proved, that some kinds of sarcocoele have yielded to the exhibition of emetics, (*Warner, Pringle, and Home in Chemical Experiments*); to a decoction of *ononis spinos.* (*Bergius Mat. Med. Richter's Chir. Bibl. 7 B. p. 605*); to *cicuta* and bark (*Warner*); to mercurial frictions (*Le Dran, B. Bell, Richerand, Delpech*); to the external use of the liquor ammon. acetatis (*Richter's Chir. Bibl. 5. B. p. 127*); to poultices containing opium (*Fothergill, in Med. Obs. and Eng. Vol. 5.*); to a lotion made of a strong decoction of hemlock (*Warner*); to the steam of vinegar, the repeated employment of leeches, and the application of cold, &c. The operation of all these means will be advantageously assisted by the continual use of a bag-truss, the observance as much as possible of an horizontal position, and attention to a suitable low diet.

Mr. Pott believed, that the man, who has the misfortune to be afflicted with a sarcocoele, has very little chance of getting rid of the disease by any plan, except extirpation; and all the time the operation is deferred, he carries about him a part, not only useless, but burdensome, and which is every day liable to become worse, and unfit for such an operation. Now, although there is a great deal of truth in this opinion, yet, I conceive, it is rather exaggerated, and that it would tend to authorize the practice of castration to an extent beyond all necessity. I certainly think, with Mr. Pott, that there never was a sarcocoele cured, where the organization of the testicle had been destroyed by disease, or where its structure had suffered so much as to render it incapable of the office, for which it is destined. But, such state cannot always be known by inspection, or manual examination, and were a surgeon to condemn to the knife every testicle, which he finds affected with indolent swelling and induration, he would remove many, which, under some of the above plans of treatment, might be perfectly cured. That there are some chronic enlargements of the testicle, which may be resolved, is a truth, of which experience

must have convinced the generality of surgeons.

The scrophulous induration, and several other swellings of this organ, which are very imperfectly understood, may sometimes be benefited, and even entirely cured, just like some analogous affections of the breast. What is termed the *venereal sarcocoele* (Mr. Pott allows) always gives way to a mercurial course properly conducted. The diagnosis of this case, it must be confessed, is not very clearly explained by surgical writers, nor was its reality acknowledged by Mr. Hunter. According to Mr. Pott, it is seldom an early symptom, and he does not remember ever to have seen an instance, in which it was not either immediately preceded, or accompanied by some other appearances plainly venereal. He adds, that it has neither the inequality, nor darting pains of scirrhus. But, the question whether the case is truly syphilitic or not, is far less interesting, than the question, whether there are not many sarcocoeles, which may be diminished and cured by mercury? The affirmative cannot be questioned. I have seen many such cases myself, and there are numerous examples on record. A statement of several has been lately published by Richerand. (See *Nosographic Chirurgicale*, Tom. 4, p. 300 *et seq.* Edit. 4.) The authority of Delpech is also on the same side. (*Précis Élémentaire des Maladies Reputées, Chir. Tom. 3, p. 564.*)

Indeed, this last writer maintains, that many common sarcocoeles and scirrhi of the testicle are so much alike in their symptoms, that the difference of their nature cannot always be at once detected by the practitioner. Hence, although I am an advocate for the early performance of castration in cases of sarcocoele, where there is reason to suppose the disease so far advanced, that the organization of the testicle is totally destroyed; or where internal and external remedies have been tried a certain time in vain; yet, these sentiments do not incline me to recommend the operation for other examples, in which the disease is quite recent, and no plan of treatment whatsoever has been fairly tried. I have already enumerated various plans of treatment, which have been proved by experience to be sometimes capable of affording relief. The disease of the testicle, which is usually called the *scrophulous sarcocoele*, like other forms of scrophula, often gets well spontaneously after a certain time, and it may frequently be considerably benefited by administering internally the conium maculatum and small doses of the submuriate of mercury; lotions of seawater, or poultices of sea-weeds, being applied to the scrotum. Several other indolent enlargements of the testicle yield to frictions with camphorated mercurial oint-

ment on the scrotum. The late Mr. Ramsden thought, that some sarcoceles might be relieved by removing with bougies a supposed morbid irritability of the urethra, with which his theories led him to connect the origin of the complaint. (See *Pract. Obs. on Sclerocele, &c.*) The novelty of this suggestion for a time attracted considerable notice; but, the interest, which it once excited, has now died away; a sufficient proof, to my mind, that the practice inculcated was not of much value.

From the preceding observations, it may be inferred, that all chronic enlargements of the testicle are not incurable; but, that we ought at the same time to be duly impressed with the expediency of not wasting too much time in the trial of means, which are not to be depended upon, and which, if continued immoderately long, might allow the disease to advance too far to be capable of being afterwards effectually extirpated.

The following observations, amongst others made by the celebrated Mr. Pott, on the circumstances, in which the operation of castration is advisable, or not, are highly valuable, and merit the serious attention of every surgical practitioner.

“These circumstances are of two kinds, and relate either to the general habit of the patient, and the disorders and dispositions of some of the viscera, or to the state of the testicle, and spermatic chord.

“A pale, sallow complexion, in those who used to look otherwise; a wan countenance, and loss of appetite and flesh, without any acute disorder; a fever of the hectic kind; and frequent pain in the back and bowels, are, in those who are afflicted with a scirrhus testicle, such circumstances as would induce a suspicion of some latent mischief, and incline one to suppose that the same kind of virus, which had apparently spoiled the testis, may also have exerted its malignant influence on some of the viscera; in which case, success from the mere removal of the testicle is not to be expected. They, whose constitutions are spoiled by debauchery and intemperance, previous to their being attacked with this disease; who have hard livers, and anasarcaous limbs, are not proper subjects for such an operation. Hard tumours within the abdomen in the regions of the liver, spleen, kidneys, or mesentery, implying a diseased state of the said viscera, are very material objections to the removal of the local evil in the scrotum. In short, whenever there are manifest appearances, or symptoms of a truly diseased state of any of the principal viscera, the success of the operation becomes very doubtful; more especially, if such symptoms and appearances, upon being properly treated, resist in such man-

ner, as to make it most probable, that a cancerous virus is the real cause of them. When none of these require our attention, the object of consideration is the testicle and its spermatic vessels. The state of the mere testis can hardly ever be any objection to the operation; the sole consideration is the spermatic chord: if this be in a natural state, and free from disease, the operation not only may but ought to be performed, let the condition of the testicle be what it may; if the spermatic chord be really diseased, the operation ought not to be attempted.

“All writers on this subject agree in saying, that if the spermatic process has partaken of the diseased state of the testicle, that is, has become enlarged and hardened, and such enlargement and induration extends itself quite up to the abdominal muscle, that the operation of castration ought not to be performed, because it will not only prove successful, but will hasten the death of the patient. And this is, in some degree, most certainly true; but not without some limitation. A truly and absolutely diseased state of the spermatic chord, in any part of it, is certainly a very material objection to the operation, as it most commonly proves a bar to the success of it: and a morbid state of the same chord quite as high as the abdominal muscle, that is, of all that part of it, which is external to the cavity of the belly, is a just and full prohibition against such attempt. But, on the other hand, it must be observed, that every apparently morbid alteration of the spermatic chord is not really such; and, therefore, that every enlargement, induration, fulness, &c. which seems to alter the spermatic vessels from that state, which is called a healthy and natural one, is not to be regarded as a disease; at least, not as such a disease as is sufficient to prohibit the attempt to obtain a cure by extirpation.

“When the spermatic vessels are not only turgid and full, but firm and hard; when the membrane, which invests and connects them, has lost its natural softness and cellular texture, and has contracted such a state, and such adhesions, as not only greatly to exceed its natural size, but to become unequal, knotty, and painful, upon being handled, and this state has possessed all that part of the chord, which is between the opening in the oblique muscle and the testicle, no prudent, judicious, or humane man, will attempt the operation; because he will, most certainly, not only do no good to his patient, but will bring on such symptoms as will most rapidly, as well as painfully destroy him.

“On the other hand,” says Pott, “every

enlargement of the spermatic chord is not of this kind, nor by any means sufficient to prohibit or prevent the operation.

"These alterations, or enlargements, arise from two causes, viz. a varicose dilatation of the spermatic vein, and a collection, or collections, of fluid in the membrane investing and enveloping the said vessels. In the first place, as there is no reason in nature why a testicle, whose vessels have previously (for some time perhaps) been in a varicose state, should not become scirrhus; so it is also clear, that the scirrhusity seizing such testicle will by no means remove, or even lessen such varicose dilatation of the vessels from which it is dependent; on the contrary, will, most probably, and indeed does most frequently, increase such distention: but such mere varicose enlargement of the vessels, whether it be previous or consequential to the morbid state of the testis, does not, nor ought to prevent the removal of it, if otherwise fit and right.

"In the next place, the diseased state of a truly scirrhus testicle, its weight, and the alteration that must be made in the due and proper circulation of the blood, through both it and the vessels from which it is dependent, may and do concur in inducing a varicose dilatation of the spermatic vein, without producing that knotty, morbid alteration and hardness, which forbid our attempts. Between these, a judicious and experienced examiner will generally be able to distinguish.

"In the former (the truly diseased state), the chord is not only enlarged, but feels unequally hard and knotty; the parts of which it is composed are undistinguishably blended together; it is either immediately painful to the touch, or becomes so, soon after being examined; the patient complains of frequent pains shooting up through his groin into his back; and from the diseased state of the membrane composing the tunica communis, such adhesions and connexions are sometimes contracted, as either fix the process in the groin, or render it difficult to get the finger and thumb quite round it.

"In the other (the mere varicose distention) the vessels, though considerably enlarged and dilated, are nevertheless smooth, soft, and compressible; the whole process is loose and free, and will easily permit the fingers of an examiner to go quite round it, and to distinguish the parts of which it is composed; it is not painful to the touch; nor does the examination of it produce, or occasion, those darting pains, which almost always attend handling a process malignantly indurated.

"The other circumstance, which I have mentioned as capable of deceiving an operator, and inducing him to believe, that

the spermatic chord is much more diseased than it really is, and thereby deterring him from the performance of an operation, which might prove successful, is the extravasation, or collection of fluid in the cellular membrane enveloping the spermatic vessels, between the abdominal opening and the testis.

"In the cellular membrane, leading to a diseased testicle, it is no very uncommon thing to find collections of extravasated fluid. These, as they add considerably to the bulk, and apparent size of the process, make the complaint appear more terrible; and, as I have just said, less likely to admit relief.

"When the extravasation is general, through all the cells of the investing membrane, and the spermatic vessels themselves are hardened, knotty and diseased, the case is without remedy; for, although a puncture, or an incision, will undoubtedly give discharge to some, or even the greatest part of the fluid; yet this extravasation is so small, and so insignificant a circumstance of the disease, that the parts, in this state, are so little capable of bearing irritation, that an attempt of this kind must be ineffectual, and may prove mischievous.

"But, on the other hand, collections of water are sometimes made in the same membrane, from an obstruction to the proper circulation through the numerous lymphatics in the spermatic process, while the vessels themselves are really not diseased, and therefore very capable of permitting the operation. In this case, the fluid is generally in one cyst, or bag, like to an encysted hydrocele, and the spermatic chord, cyst and all, are easily moveable from side to side; contrary to the preceding state, in which the general load in the membrane fixes the whole process, and renders it almost immovable.

"A discharge of the fluid will, in this case, enable the operator to examine the true state of the process, and, as I have twice or thrice seen, put it into his power to free his patient from one of the most terrible calamities which can befall a man." (See *Pott on Hydrocele, &c.*)

The testicle is subject to a disease often called *soft cancer*, which, though of a very malignant and incurable nature, is different from the true cancer, already described. It has been particularly noticed by Mr. Abernethy, under the name of *Medullary Sarcoma*. In most of the instances, which this gentleman has seen, the tumour, when examined after removal, has appeared to be of a whitish colour, resembling on a general and distant inspection, the appearance of the brain, and having a pulpy consistence. Mr. Abernethy has also often seen it of a brownish red appear-

ance. The following case is related, to illustrate the nature and progress of the disease.

"A tall, thin, healthy-looking man, of about forty years of age, had, about fifteen years before, a swelled testicle from a gonorrhœa; the epididymis remained indurated. Six years afterwards it became enlarged, and a hydrocele at the same time formed. Half a pint of water was discharged by a puncture, but inflammation succeeded the operation, and this testis became very large. An abscess formed, and burst in the front of the scrotum, and the testis subsided in some degree. Mercury was employed to reduce it, but without effect. The part, however, was indolent, and gave the patient no trouble but from its bulk.

"About a year afterwards, a gland enlarged in the left groin (the same side as the testis): another then became swollen in the right groin, and, in the course of two years, several glands in each groin had obtained a very considerable magnitude. At this period, he was admitted into St. Bartholomew's Hospital, under the care of Mr. Long. The testis was, at this time, between four or five inches in length, and about three in breadth; it resembled its natural form, and was indolent in its disposition. The spermatic chord was thickened, but not much indurated. Four or five glands were enlarged in the groin on both sides; each of which was of the size of a very large orange; and when observed together, they formed a tumour of very uncommon shape and magnitude.

"They gradually increased in size for several months, till at last the skin appeared as if unable to contain them any longer. It became thin, inflamed, and ulcerated, first in the left groin, and thus exposed one of the most prominent tumours. The exposed tumour inflamed and sloughed progressively, till it entirely came away. As the sloughing exposed its vessels, which were large, they bled profusely, insomuch that the students endeavoured, but in vain, to secure them by ligatures: for the substance of the tumour was cut through, and torn away in the attempt. Pressure by the finger, continued for some time, was the only effectual mode of restraining this hemorrhage.

"The loss of one gland relieved the distended skin, which had only ulcerated on the most prominent part of the tumour, and had not become diseased. It now lost its inflamed aspect: granulations formed, and a cicatrix took place. In the opposite groin a similar occurrence happened. One gland, exposed by the ulceration of the skin, sloughed out, being attended by the circumstances just

recited. However, before the skin was cicatrized, ulceration had again taken place in the right groin, in consequence of the great distention of the skin from the growth of the tumour; and sloughing had begun in the tumour, when the patient, whose vital powers had long been greatly exhausted, died." (See *Surgical Observations*, &c. 1804, by J. Abernethy, F. R. S. &c.)

The preceding kind of disease bears a considerable resemblance to fungus hæmatodes; but differs in the parts sloughing out, and then healing, instead of a fungus shooting out, and continually increasing in size. (See *Fungus Hæmatodes*.)

Dr. Baillie has noticed some affections, in which the testicle becomes bony, cartilaginous, &c.; but, on these it is not necessary for us to dwell in this dictionary. The preceding observations may be considered as relating expressly to the diseases for which castration is generally performed. See *Castration*.

Besides the fungus, which arises from the testicle in the advanced stage of carcinoma, and the bleeding fungous growth, which arises from this organ in the ulcerated state of fungus hæmatodes, there is another superficial fungous excrescence, to which the testicle is subject, and which is entirely free from all malignancy. The disease, to which I refer, has been noticed by Callisen, under the name of *lipoma of the testicle*. "Si ex superficie albugineæ vel ipsa tunica vaginali excrescentiæ surgunt, totum demum testem involventes, et scirrhum seu fungum, mentientes, ipsius tamen testis substantia parum aut vix de statu naturali aberrante; malum naturam lipomatis sequitur, vix unquam in scirrhum et carcinoma abiens." (See *Systema Chirurgiæ Hodiernæ*, Vol. 2, p. 145, Edit. 1800.) The superficial fungus, or *lipoma of the testicle*, was noticed in an early edition of another publication, and described as "a particular affection of the testicle, in which a fungus grows from the glandular substance of this body, and, in some instances, from the surface of the tunica albuginea. This excrescence is usually preceded by an enlargement of the testicle, in consequence of a bruise, or some species of external violence. A small abscess takes place, and bursts, and from the ulcerated opening the fungus gradually protrudes." I then proceeded to represent how unnecessary and improper it was to extirpate the testicle, on account of this affection, if, after the subsidence of the inflammation, the part should not seem much enlarged and indurated. I recommended the fungus to be cut off, or else destroyed with caustic; and I founded my advice on a successful attempt of the first kind, which was made in St. Bartholomew's Hospital, by Sir James Earle, a little while before my book was

published. (See *First Lines of the Practice of Surgery*, p. 399.)

An interesting little paper has also been written on the subject, by my friend Mr. Lawrence, who has favoured the public with a more particular account, and nine cases illustrative of the causes, symptoms, and progress of the disorder. According to Mr. Lawrence, the patient generally assigns some blow, or other injury, as the cause of the complaint; in other instances, it originates in consequence of the hernia humoralis from gonorrhœa, and sometimes appears spontaneously. A painful swelling of the gland, particularly characterized by its hardness, is the first appearance of the disease. After a certain length of time, the scrotum, growing gradually thinner, ulcerates; but, the opening, which is thus formed, instead of discharging matter, gives issue to a firm, and generally insensible fungus. The surrounding integuments and cellular substance are thickened and indurated by the complaint, so that there appears to be altogether a considerable mass of disease. The pain abates, and the swelling subsides considerably, when the scrotum has given way. In this state, the disorder appears very indolent; but if the fungus be destroyed by any means, the integuments come together, and a cicatrix ensues, which is inseparably connected with the testicle. Mr. Lawrence next informs us, that if the part be examined while the fungus still remains, the excrescence is found to have its origin in the glandular substance of the testicle itself; that the coats of the part are destroyed to a certain extent; and that a protrusion of the tubuli seminiferi takes place through the aperture thus formed. Mr. Lawrence says, he has often ascertained the continuity of the excrescences with the pulpy substance of the testicle, of which more or less remains, according to the difference in the period of the disorder. The same gentleman thinks, that the glandular part of the testicle experiences an inflammatory affection in the first instance, in consequence of the violence inflicted on it; and that the confinement of the swollen substance, by the dense and unyielding tunica albuginea, sufficiently explains the peculiar hardness of the tumour, and the pain which is always attendant on this stage of the disorder. The absorption of the coats of the testis, and of the scrotum, obviates the tension of the parts, and thereby restores ease to the patient, at the same time that the fungus makes its appearance externally.

With regard to the treatment, Mr. Lawrence is of opinion, that, if the complaint were entirely left to itself, the swelling would probably subside, the fungus shrink, and a complete cure ensue, without any professional assistance; but, he adds, that

the disorder is so indolent in this stage that a spontaneous cure would not be accomplished till after much time. He says, that the excrescence may be removed with a knife, or, if the nature of its attachment permit, with a ligature, or that it may be destroyed with escharotic applications. Mr. Lawrence very judiciously gives the preference to removing the tumour to a level with the scrotum, by means of the knife, as the most expeditious and effectual mode of treatment. He can discern no ground whatever for proposing castration in this malady, since, in no part of its progress, nor in any of its possible consequences and effects, can it expose the patient to the slightest risk.

Mr. Lawrence also mentions the possibility of there being other kinds of funguses, which may be met with, growing from the testicle, and quotes an instance, in which Dr. Macartney found a fungus, of a firm and dense structure, growing from the tunica albuginea, while all the substance of the testicle itself was sound. Dr. Macartney was so kind as to shew me the preparation, affording a clear specimen of the second kind of fungus. The cases drawn up by Mr. Lawrence are, in my opinion, highly interesting, and may be read in the *Edinb. Med. and Surgical Journal* for July, 1808.

We have seen, that Callisen represents the lipoma, as sometimes originating from the surface of the tunica vaginalis, a kind of case, which has not yet fallen under my observation.

TETANUS. (from *τείνω*, to stretch.) Tetanus is defined by all authors to be a more or less violent, and extensive, contraction of the muscles of voluntary motion, attended with tension and rigidity of the parts affected.

The excessive contraction of the muscles is kept up, without any intervals of complete relaxation, in which respect the disorder differs from ordinary spasms and convulsions, where the contractions and relaxations alternate in rapid succession. In tetanus, the powers of sensation and intellect also remain unimpaired, in which particularity it forms a contrast to epilepsy. (*Rees's Cyclopaedia*, Art. Tetanus.)

When its effects are confined to the muscles of the jaw or throat, it is called *trismus*, or *locked-jaw*; when all the body is affected and becomes rigid, but retains its ordinary straightness, the case is named *tetanus*. When the body is bent forwards, the disease is termed *emprostotonos*; and *opisthotonos*, when the muscles of the back are principally affected.

To these four forms, some writers have added a fifth, which they denominate *pleurosthotonos*, and which is characterized by the body being drawn to one side. It is the *tetanus lateralis* of Sauvages.

The different terms, which are applied to tetanic affections, do not imply so many particular diseases; but, only the seat and various degrees of one and the same complaint.

A far more important division of tetanus, is into the *acute* and *chronic*, according to its greater or lesser intensity. The first is exceedingly dangerous, and usually fatal; while the latter, on account of the more gradual progress of the symptoms, affords more opportunity of being successfully treated. (*Larrey, in Mém. de Chirurgie Militaire, Tom. 1, p. 235, 236.*)

Tetanus may also be distinguished into the *traumatic*, or that arising from wounds, being the case with which surgeons have principally to deal; and into the *idiopathic*, or that proceeding from a variety of other causes.

Traumatic tetanus sometimes comes on in surprisingly sudden manner, and quickly attains its most violent degree. The most rapidly fatal case, that has ever been recorded, is one, that we have on the authority of the late Professor Robison of Edinburgh. It occurred in a negro, who scratched his thumb with a broken china plate, and died of tetanus a quarter of an hour after this slight injury. (*See Rees's Cyclopædia, art. Tetanus.*) But, commonly, the approaches of the disorder are more gradual, and it slowly advances to its worst stage. In this sort of case, the commencement of the disorder is announced by a sensation of stiffness about the neck, a symptom, which increasing by degrees, renders the motion of the head difficult and painful. In proportion as the rigidity of the neck becomes greater, the patient experiences about the root of the tongue, an uneasiness, which soon changes into a difficulty of mastication and swallowing, which after a time become totally impossible. The attempt at deglutition is attended with convulsive efforts, especially when an endeavour is made to swallow liquids; and so great is the distress, which accompanies these convulsions, that the patient becomes very reluctant to renew the trials, and refuses all nourishment. Sometimes it even inspires him with a dread of the sight of water, and a great resemblance to hydrophobia is produced.

One of the next remarkable symptoms is a very severe pain at the bottom of the sternum, darting from this point backward to the spine, in the direction of the diaphragm. As soon as this pain commences, the spasms of all the muscles about the neck become exceedingly violent, and the head is drawn backwards, or forwards, according as the contraction of the extensor, or flexor muscles, happens to be strongest; but, in the majority of cases, the head and trunk are curved backwards, (*Boyer Traité des Mal. Chir. Tom. 1, p. 288.*) and the con-

tractions increasing in force, the body is frequently raised in the form of a bow, resting upon the head and feet alone; a state, which is more particularly denominated *opisthotonos*. (*Rees's Cyclopædia, art. Tetanus.*) At the same time, the muscles, which close the lower jaw, and which were affected with spasm and rigidity in the very beginning of the disorder, now contract with great power, so as to maintain the lower jaw-bone inseparably applied to the upper one. This last state, which has been considered as a particular affection under the name of *trismus*, or the *locked-jaw*, Boyer conceives, may be regarded as the pathognomonic symptom of tetanus, which in many instances is limited to such an affection of the jaw.

The muscles affected in tetanic cases are never altogether relaxed, as long as the disease continues; but, still they become more violently contracted in the frequent paroxysms of spasm, which always attend the complaint, and increase as it advances.

The continuance of the disease is marked by the increasing spasm of the diaphragm, which now returns every ten or fifteen minutes, and is instantly succeeded by a stronger retraction of the head and rigidity of the muscles of the back, and even of those of the lower extremities. The abdominal muscles are also strongly contracted, so that the belly feels as hard and tense as a board. By the violence of the contractions, indeed, the recti muscles have been known to be lacerated, as we shall relate an example of hereafter. Sometimes the spasm and tension extend only to the muscles on one particular side of the body: the *tetanus lateralis* of Sauvages, and the *pleurosthotonos* of other nosologists.

When the disease reaches its most violent stage, the flexor muscles of the head and trunk contract so powerfully, that they counterbalance the force of the extensors, and hold those parts in a straight, fixed, immoveable position. This is the condition, to which the appellation of *tetanus*, more particularly belongs. The muscles of the lower extremities become rigid; and even the arms, which till now were little affected, also partake of the general spasm and stiffness, with the exception of the fingers, which often retain their moveableness to the last. The tongue likewise continues a long while endued with the power of voluntary motion; but, at length, the violent spasms do not leave it unaffected, and it is then liable to be forcibly propelled between the teeth, where it is sometimes dreadfully lacerated.

In the extreme period of the disorder, all the muscles destined for voluntary motion are affected; amongst others, those of the face; the forehead is drawn up into

furrows; the eyes, sometimes distorted, are generally fixed and motionless in their sockets; the nose is drawn up; and the cheeks are retracted towards the ears; so that the features undergo a most extraordinary change. When tetanus arrives at this stage, and the spasms are universal, a violent convulsion usually puts an end to the patient's misery.

Wherever the muscular contractions are situated in cases of tetanus, they are always accompanied with the most excruciating pain. They sometimes last, without any manifest remission, to the end of the disorder; but, in almost all cases, their violence, and the sufferings excited by them, undergo periodical diminutions every minute, or two. The relaxation, however, is never such as to let the muscles, which experience it, yield to the action of their antagonists; and it is in nearly all cases followed, in ten or twelve minutes, by a renewal of the previous contractions and suffering. The recurrence of these aggravated spasms frequently happens, without any evident cause; but, it is often determined by efforts, which the patient makes to change his posture, swallow, speak, &c.

As Dr. Cullen observes, the attacks of this disease are seldom attended with any fever. When the spasms are general and violent, the pulse is contracted, hurried, and irregular; and the respiration is affected in like manner; but, during the remission, both the pulse and respiration usually return to their natural state. The heat of the body is commonly not increased; frequently the face is pale, with a cold sweat upon it; and, very often, the extremities are cold, with a cold sweat over the whole body. When, however, the spasms are frequent and violent, the pulse is sometimes more full and frequent, than natural; the face is flushed, and a warm sweat is forced out over the whole body.

"Although fever be not a constant attendant of this disease, especially when arising from a lesion of nerves; yet, in those cases, proceeding from cold, a fever sometimes has supervened, and is said to have been attended with inflammatory symptoms. Blood has often been drawn in this disease; but, it never exhibits any inflammatory crust; and all accounts seem to agree, that the blood drawn seems to be of a looser texture than ordinary, and that it does not coagulate in the usual manner.

"In this disease the head is seldom affected with delirium, or even confusion of thought, till the last stage of it; when by the repeated shocks of a violent distemper, every function of the system is greatly disordered.

"It is no less extraordinary, that in this violent disease, the natural functions

are not either immediately, or considerably affected. Vomitings sometimes appear early in the disease; but commonly they are not continued; and it is usual enough for the appetite of hunger to remain through the whole course of the disease; and what food happens to be taken down, seems to be regularly enough digested. The excretions are sometimes affected, but not always. The urine is sometimes suppressed, or is voided with difficulty and pain. The belly is costive; but, as we have hardly any accounts, excepting of those cases, in which opiates have been largely employed, it is uncertain, whether the costiveness has been the effect of the opiates or of the disease. In several instances of this disease, a miliary eruption has appeared upon the skin, but whether this be a symptom of the disease, or the effect of a certain treatment of it, is undetermined. In the mean while, it has not been observed to denote either safety or danger, or to have any effect in changing the course of the distemper."

—(*First Lines of the Practice of Physic*, vol. 3.)

According to M. Larrey, the opisthotonos is not so often observed in Egypt as the emprosthotonos, and the experience of this gentleman taught him, that the former was the most rapidly fatal. We must not adopt, however, his curious opinion, that the violent extension of the vertebræ of the neck, and the manner, in which the head is thrown back, cause strong compression of the spinal marrow, and a permanent contraction of the larynx and pharynx, (*Mém. de Chirurgie Militaire*, Tom. 1, p. 240.) since this sort of compression, if it did not at once destroy the patient, would at any rate paralyze most of the muscles, and instantly stop their extraordinary contraction.

This experienced writer notices how much the nerves of the neck and throat seem generally to be affected on the invasion of this disease. The consequent contraction of the muscles of these parts, he says, is soon attended with difficulty of deglutition and respiration. The patients then experience, if not a dread of liquids, at least a great aversion to them, which often prevents the administration of internal remedies; and if the wound is out of reach of the interference of art, the patient is doomed to undergo the train of sufferings attendant on this cruel and terrible disorder. Nothing can surmount the obstacles, which present themselves in the œsophagus. The introduction of an elastic gum catheter into this canal, through the nostrils, is followed by convulsions and suffocation. "I have tried this means (says Larrey) on the person of M. Navailh, a surgeon of the second class, who died of a locked-jaw,

brought on by a wound of the face, accompanied with a comminuted fracture of the bones of the nose, and part of the left orbit.

"In the examination of the bodies of persons dead of tetanus, I have found the pharynx and œsophagus much contracted, and their internal membrane red, inflamed, and covered with a viscid reddish mucus.

"Hydrophobia, hysteria, and several other nervous diseases, likewise produce their chief effects upon these organs, and the result appears to be the same. So, I have just remarked, when tetanus is arrived at its worst degree, the patients have a great aversion to liquids, and, if they are forced to swallow them, immediate convulsions are excited. This circumstance was particularly observed in M. Navailh."—(*Mém. de Chirurgie Militaire*, Tom. 1. p. 247, 248.)

Sometimes tetanic affections deviate from their ordinary course and nature. The most singular of these anomalies is recorded by Sir Gilbert Blane; it is a case, in which tetanus prevailed to a very considerable extent, without any degree of pain. The spasms were accompanied with a tingling sensation, which was even rather agreeable than distressing. The case, however, terminated fatally; but, to the last, no pain was experienced. In two examples, mentioned by the same author, the spasms affected only the side of the body, in which the wound was situated.

The dissection of patients, who have died of tetanus, has thrown no light upon the nature of this fatal disorder. Sometimes, slight effusions are found within the cranium; but, in general, no morbid appearance whatever can be detected in the head. There is always more or less of an inflammatory appearance in the œsophagus and in the villous coat of the stomach about the cardia. But those, who are conversant with dissections, must be well aware, that these appearances are common to a great number of diseases, and are uniformly met with in every case of rapid, or violent death. Besides the redness and increased vascularity of these parts, M. Larrey, as we have already stated, found the pharynx and œsophagus much contracted, and covered with a viscid reddish mucus. He also found numerous lumbrici in the bowels of several patients who died.—(*See Mém. de Chir. Militaire*, Tom. 3. p. 287.) This, however, could only be an accidental complication, and not a cause. In several cases, Dr. M'Arthur found the intestines much inflamed, and in two of them a yellow, waxy fluid, of a peculiar offensive smell, covered their internal surface; but, whether the inflammation was primary, or only a consequence of the pressure of the abdominal muscles, which contract so violently in this disease, he is unable to decide.—(*See Medico-Chi-*

rurgical Trans. Vol. 7, p. 475, and *Rees's Cyclopædia*, art. Tetanus.)

Dr. Lionel Chalmers, of Charles Town, South Carolina, states, that when the disease forms very quickly, and invades the unfortunate person with the whole train of its mischievous symptoms, in a few hours, the danger is proportioned to the rapidity of the attack, and that the patients thus seized, generally die in 24, 36, or 48 hours, and very rarely survive the third day. But, when the disease is less acute, few are lost after the ninth, or eleventh. (*See Med. Obs. and Inq.* vol. 1. p. 92, 93.)

From the valuable report of Sir James Macgrigor, it appears, that several hundreds of cases of tetanus occurred in our army, during the late campaigns in Spain and Portugal. The disease was observed to come on at uncertain periods after the receipt of the local injury; but, it terminated on the second, third, and fourth days, and even as late as the seventeenth and twentieth day; though it was usually not protracted beyond the eighth.—(*Medico-Chir. Trans.* Vol. 6, p. 453.)—I had a patient, however, who lingered in the military hospital at Oudenbosch five weeks, with chronic tetanus, before he died. This happened in the year 1814, soon after the assault on Bergen-op-Zoom, where the patient had been wounded, and suffered amputation of the thigh.

Although tetanus is a disease, which has been observed, in almost all parts of the world, experience proves, that its frequency is much the greatest in warm climates, and especially in the hot seasons of those climates. It is also more common in marshy situations, and countries bordering upon the sea, than in places which are very dry, elevated, and at a distance from the sea-coast. Every class of individuals is exposed to its attacks; but, infants a few days after their birth, and middle-aged persons, are said to be oftener affected, than older subjects, or others in the youthful period of life. The male sex more frequently suffer, than the female; and the robust and vigorous more frequently, than the weaker.

According to Dr. Cullen and other medical writers, the causes of tetanus, are cold and moisture, applied to the body, while it is very warm, and especially the sudden vicissitudes of heat and cold. Or the disease is produced by punctures, lacerations, or other injuries. Cullen admits, however, that there are probably some other causes, which are not distinctly known.

M. Larrey observed, that gunshot wounds in the course of the nerves, and such injuries of the joints, often produce tetanus in the climate of Egypt, particularly when the weather, or temperature, passed from one extreme to the other, in damp situations, and in those which were adjacent to the Nile, or the sea. What he terms dry and

irritable temperaments, were the most subject to the disorder, the event of which was found to be almost always fatal. (*Larrey, Op. et Loc. cit.*)

Traumatic tetanus is remarked to proceed oftener from wounds of the extremities, than from similar injuries of the trunk, head and neck. Sometimes, it originates at the moment of the accident, as in the instance mentioned by the late Professor Robison of Edinburgh; but, in general, it does not come on till several days afterwards, sometimes not till the wound is nearly, or perfectly healed, and free from all pain and uneasiness. Wounds of every description may give rise to tetanus, and in warm climates, very trivial injuries produce it. Thus, in Egypt, M. Larrey had one case, which proceeded from the lodgment of a small piece of fish bone in one of the sinuses of the fauces. (*Mém. de Chirurgie Militaire, Tom. 1, p. 254.*) There can be no doubt, however, that in colder regions, traumatic tetanus seldom happens except from contused, punctured, or lacerated wounds; or wounds of the ginglymoid joints, with laceration of the tendons and ligaments; compound fractures, or dislocations; deep pricks in the sole of the foot; and especially lacerations of the fingers and toes. A partial division of a nerve has been suspected as a cause; but, as some nerves must be imperfectly cut through in almost every wound, and yet tetanus does not arise, the reality of this cause is doubtful. Besides, if it were true, the cure would be easily effected by making the division of the nerve complete, which experience contradicts. Baron Larrey, however, has recorded a fact, which favors the opinion, as I shall presently notice. The inclusion of the nerves in the ligatures applied to arteries is another alleged cause of tetanus; but, as this fault is very common, and tetanus rather rare in this country, while it may follow all sorts of wounds, whether accidents, or operations, the accuracy of this opinion may also be doubted. In support of it, however, there are some cases and observations adduced by Larrey, which will be quoted in the sequel of this article. (*See Tom. 3, of his Mém. de Chir. Mil.*) I do not mean to hint, however, that the nerves are not sometimes tied in tetanic cases, or that the practice is not on every account blameable. Amputation and castration are the only great surgical operations to which I have seen tetanus succeed; though it may follow the employment of the knife on less severe occasions.

In warm countries, tetanus is an ordinary consequence of all kinds of wounds.

There cannot be a doubt, that difference of climate makes considerable difference in the degree and danger of tetanus. M. Larrey found, that, in Egypt, the disease was more intense, and bore a greater resemblance to hydrophobia, than in the colder

climate of Germany. In both these countries, he remarked, that when the wounds, causing tetanus, injured nerves situated on the forepart of the body, emprostotonos was occasioned; that if the posterior nerves were hurt, opisthotonos followed; and that when the wound extended quite through a limb, so as to injure equally both descriptions of nerves, complete tetanus ensued. He noticed, also, that the disease commonly only arose from wounds, when the seasons and temperature passed from one extreme to another. Exposure to the cold damp nocturnal air, he found particularly conducive to it. (*See Mém. de Chirurgie Militaire, Tom. 3, p. 286.*)

In the late campaigns of our armies in Spain and Portugal, according to the report of Sir James Macgrigor, tetanus occurred in every description, and in every stage of wounds, from the slightest to the most formidable: it followed the healthy and the sloughing; the incised and the lacerated; the most simple and the most complicated. It occurred at uncertain periods; but, it was remarked, that, if it did not commence before 22 days, from the date of the wound, the patient was safe. (*See Medico-Chirurgical Trans. Vol. 6, p. 453.*) In Egypt, as we learn from M. Larrey, the latest period of the commencement of tetanus after a wound, was from the fifth to the fifteenth day. (*Mém. de Chir. Militaire, T. 1, p. 263.*)

It is observed by Dr. Dickson, that as the acute form of tetanus is so uniformly fatal, it is of the greatest consequence to attend to whatever may assist in detecting the disease early, or in warding it off. Richerand states, that, in wounds threatening convulsions and tetanus, a persevering extension of the limbs during sleep often manifests itself, before any affection of the lower jaw; and we should naturally pay more attention to any admonition of this kind in punctured, or extensive lacerated wounds, particularly of tendinous, or ligamentous parts, and especially in injuries of the feet, hands, knee-joint, back, &c. Some prelusive indications of danger may often be derived from the increase of pain, irritation, restlessness, nervous twitchings, pain and difficulty in deglutition, or in turning the head; spasms, or partial rigidity of some of the voluntary muscles; pain at the scrobiculus cordis; a suppressed, or vitiated state of the discharge, &c. which mark the slower approaches of the disease. M. Larrey adduces several instances of tetanus, in which the wound was either dry, or afforded only a scanty serous exudation, and where the symptoms were relieved on suppuration being re-established; and Dr. Reid, in the Edinburgh Medical and Surgical Journal for July 1815, remarks, that, on removing the dressing, the wound was covered with a darkish unhealthy-looking matter, and that he had seen this change the forerunner

of tetanus in two other instances. A torpor of the intestines has generally been observed to precede, as well as accompany the disease, and Boyer, in particular, enumerates an obstinate constipation amongst the predisposing causes. (*Traité des Mal. Chir. T. 1. p. 287.*) Mr. Abernethy also informs us, that in four cases, where he inquired into the state of the bowels, the evacuations were not like feces; and he proposes as a question, in investigating the cause, what is the state of the bowels, between the infliction of the injury, and the appearance of this dreadful malady? (*Abernethy's Surgical Works, Vol. 1, p. 104.*) Dr. Parry thinks the velocity of the circulation an useful criterion of the danger of the disease, and observes, that, if the pulse be not above 100 or 110, by the fourth, or fifth day, the patient almost always recovers; but that if it be quickened early, the disease mostly proves fatal, and yet there are a few instances of recovery, where the pulse has risen to 120 on the first day. M. Larrey remarks, that, when the perspiration, which so often attends the disease, is symptomatic, it begins upon the head and extremities; but, that when it is critical it occurs over the chest and abdomen. (*Mémoires de Chir. Militaire, Tom. 1. p. 256.*) It must be confessed, however, that, in many cases, perspiration flows very freely, without bringing relief. (*Rees's Cyclopædia, art. Tetanus.*)

I next proceed to consider the treatment of tetanus, a subject of infinite difficulty, because the disease frequently baffles every mode of practice, and in certain instances gets well under the employment of the very same remedies, which decidedly fail in other similar cases of the disorder. Every plan has occasionally succeeded, and every plan has still more frequently miscarried. The great difficulty, therefore, is to ascertain, amongst numerous discordant accounts, what practice is found on the whole to be attended with the least ill-success? For, in the present state of our knowledge, the most credulous practitioner will not flatter himself with the supposition, that any effectual remedy for tetanus has yet been discovered. As, however, tetanus was regarded by Hippocrates and the ancients as certainly mortal, and it does not always prove so in modern times, it seems allowable to conclude that the recoveries, which now happen, must be ascribed to improvements in practice. This reflection should lead us not to give up the subject as hopeless; but to redouble our exertions for the discovery of a more successful method of treatment, and, if possible, of some new medicine, possessing more specific power over the disorder.

As it is justly observed by a well-informed writer, when we reflect upon the obscurity, which involves both the *ratio symptomatum*,

and the proximate cause of tetanic affections, we need not wonder, that the practice in these disorders should still be entirely empirical. The indication of cure, which is generally applicable in all diseases, namely, the removal of the exciting causes, has but little place in a morbid condition, which is the consequence of causes, that in general have ceased to act, or which it is not in our power either to remove or control. In those cases, where we could suppose local irritation to be still operating, the most effectual method of counteracting its effects on the system, would obviously be to intercept all communication between the seat of the irritation and the sensorium. If, however, the disease has already established itself, and the severe symptoms have come on, it does not appear, that this would succeed in arresting the course of the disorder. Experience has but too fully shewn, that the amputation of the limb, from the injury of which the tetanus has arisen, will very seldom procure even a mitigation of the symptoms, if performed after a certain period from their first appearance. (*Rees's Cyclopædia, art. Tetanus.*) Baron Larrey has been the greatest modern advocate for the performance of amputation in cases where tetanus depends upon a wound of the extremities; but, the facts which he has adduced in its favour are not numerous, and he limits his recommendation of the measure chiefly to chronic cases, and extends it to no others, except on the very first accession of the symptoms.

"The equally unexpected and entire success (observes M. Larrey), obtained, by the amputation of the injured limb, in the person of an officer attacked with chronic tetanus, leads me to propose the question, whether, in this disorder, occasioned by a wound of some part of the extremities, it would not be better to amputate the injured limb immediately the symptoms of tetanus commence, rather than expect from the resources of nature, and from very uncertain remedies, a cure, which so seldom happens?"

"If tetanus is chronic, as is sometimes observed, amputation may be done at every period of the disorder, provided a choice be made of the time, when there is an intermission of the symptoms. The operation would not answer so well in acute tetanus, if the disease were advanced, and the muscles to be divided were strongly contracted and rigid, as I have observed at the siege of Acre in a soldier, who was seized with tetanus, in consequence of a gun-shot wound of the left elbow." (*Mém. de Chir. Militaire, Tom. 1, p. 262.*)

Larrey did, indeed, try amputation in a few instances of acute tetanus. In the

case last cited, the symptoms were already considerably advanced, when the experiment of amputating the arm was made; yet, says Larrey, the operation was followed by considerable ease. The symptoms recurred, however, a few hours afterwards, and proved fatal on the third day. In another example, this gentleman repeated the experiment, though acute tetanus had begun. The operation is described as having stopped all the symptoms, as it were, by enchantment; the patient even passed twelve hours in perfect ease; but, being exposed to the damp cold air, the disorder returned, and carried him off. (See *Mém. de Chirurgie Militaire*, Tom. 1, p. 263—269.) The Baron also records some cases in favour of amputation at the commencement of tetanus from wounds, and especially for the relief of the disease in its chronic form. He has likewise adduced an interesting example, in which speedy relief and a cure followed cutting off all communication between the nerves of the wounded part and the sensorium by a suitable incision.

In this place, I think it right to remind the reader, that although Baron Larrey once or twice amputated when acute tetanus was somewhat advanced, he does not advise the practice, and he expressly restricts his sanction of amputation to chronic or quite incipient cases of tetanus, and to a few instances, in which the ginglymoid joints are fractured, accidents, which independently of tetanus would generally require the operation. (See *Mém. de Chir. Mil.* Tom. 3.) The report of Sir James Macgrigor fully confirms the statement of M. Larrey; namely, that free incisions are of little avail in the acute and fully formed disease, and that amputation fails in the same kind of case. After the battle of Toulouse this operation was extensively tried; but, without success. The French are also said to have lost an immense number of soldiers from tetanus after the battle of Dresden, when Sir James infers that the practice of amputation must have been fairly tried. (See *Medico-Chirurgical Trans.* Vol. 6, p. 456.) We have seen, however, that, according to the precepts of M. Larrey, the French surgeons would only have performed the operation in chronic cases, which are not the most frequent, or if in other instances, only on the very first accession of the symptoms. But, upon the whole, notwithstanding the partial degree of success attending M. Larrey's experiments, I have no hesitation in declaring my belief, that amputation of the injured part in cases of chronic tetanus will never be extensively adopted. The uncertain efficacy of this severe measure, and the occasional possibility of curing this form of the complaint by

milder plans, will for ever constitute insuperable arguments against the practice.

On the subject of making incisions for the purpose of separating the nerves of the wounded part from the sensorium, Larrey states, that they should be practised before inflammation has come on; for, if this has made progress, they would be useless and even dangerous. They should comprehend, as much as possible, all the nervous filaments and membranous parts; but, he condemns all incisions into joints, as exasperating the symptoms of tetanus, instances of which he has witnessed. The Baron has recorded some convincing proofs of the benefit sometimes arising from completely dividing the trunk of the injured nerve. In one instance, tetanic symptoms followed an injury of the supraorbital nerve, but were immediately stopped by dividing some of the fibres of the occipito-frontalis, and the nerves and vessels, down to the bone.

On the principle of destroying the parts, which are the seat of the local irritation, Baron Larrey also frequently applied the actual and potential cautery to the wound. The application of caustics, says he, may be practised with advantage on the first attack of the symptoms, the same precept being observed as in making the incisions. Bleeding, if necessary, and the use of topical emollients and anodynes, may follow these operations; though in general they have little effect. (*Mém. de Chir. Militaire*, Tom. 1, p. 249.) In the third volume of this interesting work, p. 297, &c. are several cases, in which the cautery was employed with success. We must not conclude, however, that much dependence ought to be placed in the use of the cautery, since M. Larrey observes in another place: "The moxa and actual cautery, recommended by the Father of Medicine, have been equally unavailing. The moxa was employed at Jaffa upon three wounded men; the disease notwithstanding followed its usual course, and terminated fatally.

"I have cited a striking instance of the inefficacy of the second method, in a case of opisthotonos." (Tom. 1, p. 258.) This author also adduces some cases, which tend to support the opinion, that tetanus occasionally proceeds from the inclusion of a large nerve in the ligature applied to an artery. The son of General Darmagnac died of tetanus consequent to amputation, and upon examining the stump, the median nerve was found included in the ligature with the artery, and its extremity reddish and swollen. (*Mém. de Chir. Mil.* T. 3, p. 287.) In another case, Larrey suspected the tetanic disorder to proceed from a principal branch of the crural nerve being tied together

with the femoral artery, and he cut the ligature; but, the relief was only partial and temporary. The cautery was therefore applied deeply to the whole surface of the stump. A marked amendment took place a few hours afterwards, and the patient recovered. A diaphoretic mixture, with camphor and opium, was also exhibited. (*T. 3, p. 297.*)

Amongst other local means for the relief of tetanus, we might as well notice the employment of blisters as near as possible to the wound, or their application, or that of the ointment of cantharides, to the wound itself. Almost all modern writers have observed, that tetanus is accompanied at its commencement and in its progress with an interruption, or total cessation of suppuration in the wound. Hence, the indication to excite this process again by the means, which I have specified. Larrey seems to have adopted both plans; but, he particularly applied the ointment of cantharides to the wound itself in an early stage of the symptoms, and in cases where there not only was a suppression of the discharge, but where he suspected the nerves of the wounded part had suffered from exposure to the cold damp air, on the detachment of the sloughs. For facts, in favour of these local means, the reader must refer to the first and second volumes of the *Mémoires de Chirurgie Militaire*.

It appears also from M. Larrey's experience in Egypt, that poultices, made of the leaves of tobacco, and applied to the wounds of persons labouring under tetanus, are followed by no advantageous effect. The alkalies also proved of no service. (*Tom. 1, p. 257.*)

I shall conclude these remarks on, what may be called, the local treatment of tetanus with mentioning, that the celebrated Dr. Rush recommended the wound to be dilated and dressed with oil of turpentine. (*See Trans. of the American Philos. Society, Vol. 2*); and that our naval surgeons often use tincture of opium as a dressing.

A great degree of obscurity prevails, respecting the most eligible *general* or *constitutional* plans of treating tetanus, and, I am afraid, it must be confessed, that our internal remedies cannot be more depended upon, than the local means, already described. This opinion is fully confirmed by adverting to the discouraging fact recorded by Sir James M'Grigor, viz. that out of several hundreds of cases, which occurred in the British army during the late campaigns in Spain and Portugal, there were very few, which terminated successfully, or, in which the remedies, however varied, seemed to have any beneficial influence, after the disease had made any progress.

(*Medico-Chir. Trans. Vol. 6, p. 449.*) The possibility of doing much good by internal medicines is also sometimes totally prevented by the inability of swallowing which afflicts the patient. In short, the present state of our knowledge, respecting tetanus, will not allow us to indulge much hopes of cure from any means yet discovered, except in the chronic form of the complaint, the instances of success in the treatment of acute tetanus being by no means numerous.

Of all medicines, opium is that, which has raised the greatest expectation, and been the most extensively tried in cases of tetanus. Indeed, there cannot be a doubt, that in many chronic, mild cases, it is competent to effect a cure. But, for this purpose, it is absolutely necessary, that its use be begun from the earliest appearance of the symptoms; that it be given in very large doses; and that the doses be repeated at short intervals, so that the system be kept constantly under the influence of the remedy. It is indeed astonishing, how the system, when labouring under a tetanic disease, will resist the operation of this and other remedies, which in its ordinary state would have been more than sufficient to overpower and destroy it. Patients with tetanus will bear with impunity quantities of opium, which at any other time would have been certainly fatal. Instances are upon record of five, ten, and even twenty grains, being taken every two, or three hours, for many days, without any extraordinary narcotic effects being produced upon the sensorium. It is always advisable, however, to begin with comparatively moderate doses, such as forty or sixty drops of the tincture of opium, which may be repeated at intervals of three, or four hours, and increased at each repetition, until some sensible effect is produced on the spasms. It seems requisite to augment the dose rapidly, as the disease presses upon us every hour, and no time must be lost, while there is yet a chance of controlling its fury. The approaching closure of the jaw, and difficulty of deglutition, which may increase so as to render it hardly possible to introduce medicines into the stomach, are additional motives for pushing our remedies, before such obstacles arise. (*Rees's Encyclopædia, art. Tetanus.*) I once supposed, it might be possible to overcome this impediment by introducing a flexible catheter down the œsophagus from one of the nostrils; but the attempt to do this always brings on a violent paroxysm of spasms, attended with such a sense of suffocation, that it cannot be endured. The experience of my friend the late Mr. Cruttwell of Bath, and that of Baron Larrey, have fully proved, that no

assistance can be derived in these circumstances from the use of any flexible tubes. (See *Mém. de Chirurgie Militaire*, Tom. 1, p. 247.) Sometimes, however, the obstacle to the administration of medicines, arising from the closure of the jaw, is prevented by loss of some of the incisor teeth, and, in some instances, Baron Larrey adopted the plan of extracting two of them. This would be useless, however, when deglutition is totally hindered, as happened in one instance recorded by the latter eminent surgeon. (*Op. cit.* T. 3, p. 301.) Glysters are the only resource, when the spasm of the fauces cannot be overcome. In this way, as much as a dram of the extract of opium has been introduced into the bowels in one dose. Opiate frictions upon the jaws, throat, and other parts of the body, have been practised. Opiate plasters have also been applied to the masseter muscles and behind the ears. This external use of opium, however, can only be regarded as a feeble, and probably useless method.

As the costiveness, always produced by tetanus, is rendered still more obstinate by opium, laxative medicines and glysters should constantly accompany its employment. The testimony of the army physicians, as we learn from the report of Sir James Macgrigor, is highly in favour of a rigid perseverance in the use of purgatives, given in adequate doses to produce daily a full effect. Dr. Forbes states, that a solution of sulphate of magnesia, in infusion of senna, was found to answer better, than any other purgative; and it was daily given in a sufficient quantity to procure a copious evacuation, which was always dark-coloured and highly offensive; and, to this practice he chiefly attributes, in one severe case, the removal of the disease. (*Medico-Chir. Trans.* Vol. 6, p. 452.)

A spasmodic rigidity of the muscles being the most prominent symptom of tetanus, it was natural for practitioners to try the efficacy of some other antispasmodic medicines, besides opium, and those which have been principally the subject of experiment, are castoreum, æther, the conium maculatum, musk, camphor, and latterly, the digitalis. In many cases, opium and camphor have been exhibited together. Indeed, M. Larrey asserts, that, of all the medicines, hitherto proposed by skilful practitioners, the extract of opium, combined with camphor, and the nitrate of potassa, dissolved in a small quantity of the almond emulsion, and given in doses more or less strong, produces the most favourable effects, since patients, who have an aversion to other fluids, take with pleasure this mixture, the action of which must be promoted by bleeding, if necessary, and

blisters, under the circumstances, which have been specified. (See *Mém. de Chir. Militaire*, T. 1, p. 271.) In the same work, several cases are detailed, which were benefited by such treatment.

Although some practitioners have thought that they have seen good effects result from musk; yet the majority of practitioners, who have made trial of both this and camphor, in cases of tetanus, have found no reason to recommend these medicines. Possibly, this may be owing, in some instances, to sufficient doses not having been exhibited, or to the musk not being of a good quality. One hundred and fifty grains of musk, however, have been given in the space of twelve hours, to a young girl, thirteen years old, affected with an incipient tetanus; but, no salutary effect on the disorder was produced.

We learn also from Sir James Macgrigor, that æther, camphor, musk, and other antispasmodics, as likewise the alkalies, were tried by our military surgeons in Spain, and found unsuccessful. (*Medico-Chir. Trans.* Vol. 6, p. 458.)

From the same authority, we find, that digitalis in large doses was tried in several cases in the Peninsula; and that it, with several other medicines enumerated, failed in almost every case of acute tetanus, which occurred. (P. 454.) In one case recorded, the jaw remained fixed to the last, and the patient was never entirely free from spasms. (P. 458.) I am not acquainted with any cases, in which belladonna has been given; but, it is certainly a remedy, well worthy of trial.

Analogy has also led to the employment of the warm bath, as a plan, which seemed to promise great benefit, by producing a relaxation of the contracted muscles. But, notwithstanding this means has appeared, in a few instances, to occasion some little relief, particularly, when the practitioner has been content with mere fomentations, it generally fails, and, often, has even done mischief. This may perhaps be, in some measure, ascribable to the disturbance and motion, which the patient must necessarily undergo, in order to get into the bath; for, it is very well known, that every exertion on the part of the patient, is very apt to excite most violent paroxysms of spasm. The author of the article Tetanus, in the *Encyclopédie Méthodique*, mentions his having seen the warm bath do harm, in two or three cases, in which it was expected to do good. Though numerous writers have recommended the trial of the plan, it would be difficult to trace, in their accounts, any facts, which decidedly shew, that its adoption has ever been followed by unequivocal benefit. The warm bath was tried in Spain, and found to produce only momentary relief. (*Medico-Chir. Trans.* Vol. 6, p. 457.) Dr. Hillary, who

practised, a long while, in the warm climate of America, where tetanus is very common, disapproves of this method of treatment. He observes, that although the use of the warm bath may appear to be very rational, and promise to be useful, he has always found it much less serviceable, than emollient and anti-spasmodic fomentations; and, he also mentions, that he has sometimes seen patients die, the very moment, when they came out of the bath, notwithstanding they had not been in it more than twenty minutes, the temperature of the water being likewise not higher than 29 or 30 of Reaumur's thermometer. (See *Hillary on the Air and Diseases of Barbadoes*.)

De Haen also relates a similar fact of a patient dying, the instant he was taken out of the warm bath.

It was, in all probability, the bad effects and inefficacy of the warm bath, which induced practitioners to try what might be effected by the cold one. The advantages of the cold bath were first explained by Dr. Cochrane in the *Edinb. Medical Commentaries*; and the plan has subsequently received the praises of Dr. Wright, the eminent Dr. Currie of Liverpool, and others. Of all the remedies, which have been employed in cases of tetanus, the cold bath seems to be that, which has been attended with the greatest success. Dr. Wright has published, in the *Medical Observations and Inquiries*, Vol. 6, a paper, in which may be found a narrative of the first trials of this method, which were all successful. The plan is said to be at present preferred throughout the West Indies. The way adopted consists in plunging the patient in cold water, and in that of the sea, when at hand, in preference to any other; or else in throwing from a certain height, several pailfuls of cold water over his body. After this has been done, he is to be very carefully dried with a towel, and put to bed, where he should only be lightly covered with clothes, and take twenty or thirty drops of laudanum. The symptoms usually seem to give way, in a certain degree, but, the relief, which the patient experiences, is not of long duration, and it is necessary to repeat the same measures, at the end of three, or four hours. They are to be repeated in this manner; that is to say, at such intervals, until those of freedom from the attacks of the disorder increase in length. This desirable event generally soon follows, and ends in a perfect cure. Wine and bark were sometimes conjoined with the foregoing means, and seemed to co-operate in the production of the good effects. Dr. Wright concludes the account with the following remark, sent to him with a case, by Mr. Drummond, of Jamaica—"I am of opinion, that opiates and the cold bath will answer every intention in the tetanus and such like

diseases; for, whilst the opium diminishes the irritability, and gives a truce from the violent symptoms, the cold bath produces that wonderful tonic effect, so observable in this, and some other cases. Perhaps, the bark, joined with these, would render the cure more certain. May we not then have failed in many cases, by using opiates alone in large doses, or, what probably is worse, with the warm bath, instead of the cold bath? And have we not reason to suspect that the increased doses of opium, that seemed requisite, when the warm bath was used, may have proved pernicious?" (Vol. 6, p. 161.)

Our army surgeons, who were in Spain, are said to have found the cold bath worse than useless, (*Medico-Chir. Trans.* Vol. 6, p. 254); and here I beg to remark particularly, that the plan seems to present no hope of benefit in cases of tetanus from wounds, however strong the evidence is of its utility in other examples of the disease. This was the opinion of Dr. Cullen, and it is adopted by Callisen, who observes; "Immersio subita iterata totius corporis in aquam frigidam in tetano a causa interna mire prodest, in tetano a causa externa minorem effectum præstat." (*Systema Chirurgiæ Hodiernæ, Pars 1. p. 169—170, Edit. 1798.*) On the subject of cold effusion and bathing, there are on record two cases, which are curious. One is related by Baron Larrey. It was an instance of tetanus from a gun-shot wound. The cold bath was used. The two first trials gave the patient extreme pain, and no amendment followed. The sight of the bath the next time filled him with an invincible dread of the water, into which he refused to be put. He was covered, however, with a blanket, and immersed. The tetanic stiffness was immediately increased, and dreadful convulsions excited. It became necessary to remove him directly from the bath, and put him to bed. Deglutition was from the moment utterly impeded, and the contraction of the muscles carried to the most violent degree. A tumour, about as large as an egg, suddenly made its appearance near the linea alba, below the navel. After death, this was found to be caused by a rupture of one of the recti muscles, and a consequent extravasation of blood. (See *Mém. de Chirurgie Mil.* T. 3, p. 287—289). This case is decidedly in support of the truth of what Professors Cullen and Callisen have observed. The next is not so: It is mentioned by Sir James Macgrigor, that, in the march of the guards through Gallicia, one of them was attacked with tetanus, in consequence of a slight wound of the finger. As it was impossible to think of leaving the man in the wretched village, where he was taken ill, he was carried on a bullock car, in the rear of the battalion. During the first part of the

day he was drenched with rain, the thermometer standing at 52° ; but, after ascending one of the highest mountains in Galicia, the patient was in a cold of 30° , and he was exposed from six in the morning till ten at night, when he was found half starved to death, but free from every symptom of tetanus. (See *Medico-Chir. Trans. Vol. 6, p. 450.*)

Another remedy, which is said to have frequently effected a cure in tetanus, is mercury. It has been employed in France with the greatest success, as may be seen by referring to the forty-fifth volume of the *Journal de Medecine*. This remedy, however, should be resorted to, in an early period of the disorder. Mercurial frictions are preferred, and these are to be put in practice so as to bring on a quick affection of the mouth; taking care, however, not to render the soreness and salivation too violent. Some contend, that it matters not, whether mercury be rubbed into the body, or given internally. It is generally allowed, that opium may be advantageously exhibited at the same time. This practice was first adopted in the West Indies, (see *Edinh. Physical and Literary Essays, Vol. 3.*) where it succeeded in many cases. Whatever benefit, however, may have been experienced from this plan in mild cases, it completely fails in the acute form of the disease. Mercurial frictions appeared to Baron Larrey to aggravate the symptoms, in the cases, where the plan was tried in Egypt; (*Mém. de Chir. Mil. T. 1, p. 257.*) and Dr. Emery, Mr. Guthrie, and other medical officers attached to our army in the Peninsula, tried inunction of the whole body, three times a day, with strong mercurial ointment, in unlimited quantity, with no degree of success. After the battle of Toulouse, a fatal case even occurred in a man strongly under the influence of mercury, which he had been previously using for the cure of the itch. (Sir J. Macgrigor in *Medico-Chir. Trans. Vol. 6, p. 454.*) The submuriate of mercury, combined with ipecacuanha, also proved inefficacious in acute cases; but, in chronic ones, the former medicine proves serviceable in keeping open the bowels.

Another method of treating tetanus, is that of administering the most powerful tonics and stimulants, such as wine, brandy, æther, preparations of ammonia, bark, cordials, &c. The introduction of this plan was chiefly owing to the eminent Dr. Rush, Professor of Medicine in Philadelphia, who published in the Transactions of the American Philosophical Society, vol. 2, a paper, entitled, "*Observations on the Cause and Cure of Tetanus.*" Dr. Rush considers tetanus as a disease essentially connected with debility, and he recommends for it the exhibition of the preced-

ing class of remedies. He particularly advises the liberal use of wine and peruvian bark; and, as we have already stated, when tetanus arises from a wound, he directs the dilatation of it, and dressings with oil of turpentine. Considerable success is represented as having attended such practice. Several other instances of success are also recorded by Dr. Hossack. (*American Medical Repository, Vol. 3.*)

Nothing is a more certain proof of our not being acquainted with any very effectual method of treating a disease, than a multiplicity of remedies, which are as opposite as possible in their effects. We have seen, that the celebrated Dr. Rush conceived that tetanus was a disease connected with debility, and he has recorded examples, in which it was successfully treated by tonics and stimulants. Extraordinary however as it may appear, many practitioners are advocates for venesection, especially in the early stage of tetanus. Dr. Dickson thinks, that, in a full habit, where the wound is swelled, inflamed, and painful, venesection, with free purging, and such other means, as are calculated to allay the general and local irritation, affords the fairest chance of averting the danger. (See *Medico-Chir. Trans. Vol. 7, Part 2.*) M. Larrey has also published several cases, in which bleeding had a good effect. We are informed by Sir James Macgrigor, that, in our military hospitals in Spain, venesection had a fair trial. In three cases at St. Andero, detailed by Mr. Guthrie, this was the principal remedy. One patient with tetanus, from a wound of the back part of the hand, was bled nearly *ad deliquium* several times with good effect, calomel and diaphoretics being also given, and he recovered. Another patient was bled in the same manner with such amendment, that he suffered but little from spasm, and could open his mouth very well, when he was seized with diarrhœa, which, in his debilitated state, carried him off. In the third case, which was one of acute tetanus, venesection, pushed to the utmost, totally failed. (*Op. cit. Vol. 6, p. 455—456.*)

The powerfully relaxing effects of tobacco clysters, in cases of hernia and enteritis, have suggested a trial of them in tetanus. In one very acute case, the plan was tried by Mr. Earle; but, it only afforded a temporary alleviation of the spasms, and, as it caused severe agitation, it was discontinued. According to Sir James Macgrigor, tobacco clysters, tried in the advanced stage of the disease, seemed to have no effect. He considers, however, the tobacco fume, as deserving further trial.

A remarkable case is recorded by Dr. Phillips, in which the jaw suddenly fell

upon the exhibition of an enema with oil of turpentine. (See *Medico-Chir. Trans.* Vol. 6, p. 65.)

According to Baron Larrey, frictions with oily liniments, as recommended by some authors, were tried by the French surgeons at Cairo; but, they produced no change in the state of the disease. We learn from the same authority, that the application of blisters to the throat also failed in checking the symptoms.

The Barbadoes tar, mentioned by Cullen, electricity, the colchicum autumnale, or meadow saffron, recommended by Dufresnoy, and several other means formerly in repute for their virtues in cases of tetanus, have now been fully proved by experience to possess little or no claim to this character.

THORAX, WOUNDS OF. See WOUNDS OF THE THORAX.

THROAT, WOUNDS OF. Injuries of this kind are often attended with considerable danger, on account of the great number of important parts, which are interested; but, mere cuts of the integuments of the throat and neck are not (generally speaking) dangerous cases, and do not materially differ from common incised wounds of the skin, in any other part of the body. They are not liable to be followed by any particular consequences, and require the same kind of treatment, as cuts in general do. (See *Wounds—Incised Wounds*.)

In wounds of the throat and neck, however, the larynx and trachea, pharynx and

œsophagus, the trunk of the carotid artery, and all the principal branches of the external carotid, the large jugular vein, the eighth pair of nerves, and the recurrent nerve, are all exposed to injury; some much more so, than others; but, all of them occasionally not escaping the edge of the knife, or razor, or the point of the sword, or other instruments.

It would certainly amount to absurdity, to offer an account of what is to be done, in cases attended with some part of the mischief above pointed out; for, no patient, thus wounded, would ever be found alive. Wounds of the eighth pair of nerves are universally considered by all surgeons as certainly fatal. These nerves, we know, proceed down the neck, in the same sheath of cellular substance, which includes the carotid artery, and lie on the outside of this vessel, between it and the internal jugular vein.

Wounds, either of the carotid artery, or internal jugular vein, must for the most part prove immediately fatal, in consequence of the great and sudden loss of blood, which would inevitably arise from an open, cut wound, interesting these vessels. However, were any surgeon on the spot at the moment, he should immediately tie the wounded vessel. One caution, however, is highly necessary in tying the carotid, viz. always to be sure, that the par vagum is excluded from the ligature; for were this nerve to be tied, this erroneous proceeding alone would remove every possibility of the patient's recovery.

If the mouth of the vessel could not be got at, pressure must be instantly resorted to, for the purpose of producing a temporary suppression of the hemorrhage. The surgeon should then either make the necessary enlargement of the wound in the integuments, with a due and constant recollection of the important parts near the place, or else, in the case of the carotid being injured, he should cut down to this vessel in the manner explained in the article *Aneurism*.

In lacerated wounds, the carotid artery may be injured, and yet the patient not immediately bleed to death; for, it is the nature of all wounds, attended with much laceration and contusion, not to bleed so freely as clean cuts. Mr. Abernethy has related a case, in which the carotid, and all the chief branches of it, were wounded in a man who was gored in the neck with a cow's horn; yet, death did not immediately follow, and there was time to have recourse to the ligature.

Punctured wounds might obviously injure, either the carotid, or the internal jugular vein, without the patient expiring of hemorrhage at once; because, the smallness of the wound in the skin, would sometimes hinder the fatal effusion of blood.

Often, however, when these vessels are wounded, the *par vagum* is injured at the same time, and the case is inevitably mortal, either immediately, from the direct effects both of the injury of the nerve, and sudden loss of blood, or very soon afterwards, the bleeding being of a slower, and more interrupted kind, which must depend on the lacerated nature of the wound, the small size of the opening in the vessel, or of that in the skin, &c.

Persons who attempt to commit suicide, by cutting their throats, do not often divide the carotid artery, on account of their incision being made too high up. Where the carotid arteries emerge from the chest, they are situated by the side of the trachea, and even a little more forward, than it. However, as these vessels proceed up the neck, they become more laterally situated with respect to the trachea; and when they have arrived at the upper part of the neck, where persons, who attempt to commit suicide, almost always cut, they become situated more backward, than the trachea, inclining towards the angle of the lower jaw.

The *œsophagus* is so deeply situated, lying close to the bodies of the vertebræ, and behind the trachea, that it is not often interested in any incised wounds, which do not immediately prove fatal, in consequence of the division of other important parts. We read of many cases, in which this tube is said to have been wounded, and what is usually set down as a criterion of the fact, is the passage of victuals through the wound. The writers of many of these narrations have proved themselves most grossly ignorant of anatomy, by not knowing, that wounds made above the *os hyoides*, as they frequently are, may enter the mouth, and hence the victuals may escape through the cut, without the *œsophagus*, or *pharynx*, being at all concerned.

However, no doubt, the *œsophagus* has occasionally been wounded, without the patient perishing so immediately, as not to be capable of receiving any succour. Stabs, and gunshot-wounds, might obviously injure the *œsophagus*, and leave other important parts untouched.

Even where the *œsophagus* is known to be wounded, its deep situation would prohibit us from doing any thing to the breach of continuity in the tube itself. The best plan would be to have recourse to antiphlogistic means, and to introduce a flexible elastic-gum catheter, from one of the nostrils, down the *œsophagus*, for the purpose of conveying nourishment and medicines into the stomach, without any risk of their getting out at the wound. An instrument of this kind will lie in the above situation, for any length of time, without occasioning much incon-

venience, and, besides being advantageous for injecting nourishment and medicines down the passage, and keeping them from issuing at the wound, it prevents all necessity for the wounded *œsophagus* to act, and become disturbed, when there is occasion to take any kind of liquids, whether in the way of medicine, or food. The outer wound should be brought together, and treated on common principles.

When persons cut their throats, we have explained, that they do not often divide the carotid artery, owing to their incision being usually made high up in the neck, where this vessel has attained a very backward situation. When any serious hemorrhage does arise, it is sometimes from the lower branches of the lingual artery, but most frequently, from the superior thyroideal arteries. Such arteries may occasion a fatal bleeding, which, indeed, would more frequently be the event, than it actually is, did not the patient often faint, in which state the bleeding spontaneously ceases, and gives time for the arrival of surgical assistance.

I need hardly tell the reader, that these arteries are to be tied, and that this important object is the first, to which the surgeon should direct his attention. The danger of bleeding to death being obviated, as soon as possible, the other requisite measures may be more deliberately executed.

With respect to wounds of the trachea, the same plan of conveying food and medicines into the stomach, through an elastic-gum catheter, introduced from one of the nostrils, down the *œsophagus*, is highly proper, though too much neglected. For, nothing creates such disturbance of the wound as the convulsive elevation and depression of the larynx and trachea, which are naturally attendant on the act of swallowing.

When the trachea is cut, the patient's power of forming the voice is more, or less, impaired, in consequence of the air passing into, and out of, the lungs, chiefly through the wound. Besides air, a considerable quantity of the natural mucus of the trachea is also continually coming out of the wound.

The grand means of accomplishing the union of wounds of the trachea, are a proper position of the head, and a rigorous observance of quietude. By raising the patient's head with pillows, and keeping his chin close to his breast, the edges of the wound, both in the skin and trachea, are placed in contact, even without any other assistance, unless the division of the trachea be exceedingly large. It is proper, however, to assist the effect of a suitable position with strips of sticking plaster, and also, according to most

authors, with a suture, or two. But, the necessity for sutures must depend on the extent of the division of the trachea; for, unless most of the circle of this tube be cut, and position be neglected, the wound in it will not gape. The stitches should never be passed through the lining of the trachea, as this method would be likely to make it inflame, and occasion considerable coughing, and irritation, which would have very pernicious effects on the wound.

Should there be much coughing, apparently arising from irritation and inflammation in the trachea, bleeding is proper, if other considerations do not forbid it. The spermaceti mixture with opium, is also frequently of great service. I never saw a wound of the trachea unite entirely by the first intention.

THROMBUS. (from *θρομβος*, coagulated blood.) A clot of blood. The term has also been applied to a tumour, formed by a collection of extravasated, coagulated blood, under the integuments after bleeding. When such an extravasation, though of some extent, is not considerable, it is usually called an *ecchymosis*. (See this word, and also *Bleeding, Occasional ill-consequences of.*)

A thrombus sometimes depends on the surgeon having totally divided the vein; but, much more frequently on his not having made the opening in the vessel, properly correspond to that in the skin. The patient's altering the posture of his arm, while the blood is flowing into the basin, will often cause an interruption to the escape of the fluid from the external orifice of the puncture; and, consequently, it insinuates itself into the cellular substance in the vicinity of the opening in the vein. In proportion as the blood issues from the vessel, it becomes effused between the skin and fascia, covering the muscles, in the interstices of the cellular substance, and this, with more, or less rapidity, and in a greater, or lesser quantity, according as the edges of the skin impede more or less the outward escape of the fluid. Sometimes, also, a thrombus forms after venesection, when the usual dressings, compress, and bandage, have been put over the puncture, and the patient imprudently makes use of the arm, on which the operation has been done. This is more particularly liable to happen, when a very large opening has been made in the vein.

The accident is not attended with any danger, when the extravasation is inconsiderable; for, in this circumstance, the tumour generally admits of being easily resolved, by applying to it linen, dipped in any discutient lotion. If the swelling should be more extensive, applying to it a compress wet with a solution of common

sea-salt, is deemed a very efficacious plan of promoting the absorption of the extravasated blood. Brandy, and a solution of the muriate of ammonia in vinegar, are likewise eligible applications.

It sometimes happens, that a thrombus induces inflammation and suppuration of the edges of the puncture. The treatment is now like that of any little abscess: a common linseed poultice may be applied, and any considerable accumulation of matter should be prevented by making an opening with a lancet in proper time. As soon as the inflammatory symptoms have ceased, discutients should be resorted to again, for the purpose of dispersing the remaining clots of blood, and surrounding induration.

When the quantity of blood is exceedingly large, authors generally recommend opening the tumour at once, and, despairing of the power of the absorbents to remove the extravasation, they recommended, as much of the blood as possible, to be pressed out through the incision. I believe, however, that making an opening is seldom necessary, and often brings on inflammation, and suppuration, when they might be avoided. I have never seen any case, in which there was real occasion to make an opening for the discharge of the blood. A case of this kind, however, may certainly be conceived.

THYROID GLAND DISEASED.
(See *Bronchocele.*)

THYROID GLAND, EXTIRPATION OF. That such an operation, though attended with great difficulties, is not impracticable, is proved by the following example:

On the 20th of March, 1791, a woman presented herself for admission at the Hôtel Dieu, with a tumour of the right portion of the thyroid gland. The swelling was two inches in diameter, round, hard, and attached to the right and middle part of the trachea, and it pushed outwards the sterno-mastoideus muscle. Independently of its being sensibly raised by each pulsation of the arteries, it obeyed the motions of deglutition, and in a slight degree impeded the passage of solid aliment. The patient, earnestly desiring to get rid of so inconvenient a deformity, determined to submit to its extirpation, which appeared her only resource. The danger, the length of time, and the pain necessarily annexed to the operation, were not concealed from her. Desault made a longitudinal incision through the middle of the tumour, beginning one inch above, and finishing one inch below the swelling. In the first section he cut down as far as the gland, dividing the integuments, the platysma-myoides, and some fibres of the sterno-hyoidei and sterno-thyroidei muscles. An assistant, with

the view of fixing the tumour, drew towards the left the inside edge of the wound made by the incision, whilst the surgeon detached the swelling from the sterno-mastoideus muscle. In dissecting the cellular substance which united the parts, two small arteries were divided, which were secured with ligatures. The external surface of the tumour being thus disengaged, the internal part was detached in the same way. The tumour was drawn outwards by means of a hook, that it might be separated with more ease from the trachea. In the course of this dissection, the branches of the thyroid arteries were successively tied, as fast as they were divided. The assistant, to whom the hook was confided, directed the gland from within and forwards, whilst the surgeon finished the dissection outwards and from above downwards. This part of the operation was the most minute and difficult: it was necessary by means of a sponge continually to wipe away the blood, which necessarily prevented the parts from being easily distinguished, and obliged the surgeon to divide but a little at a time, and previously to feel with his finger those parts which he was about to cut. By this cautious dissection of parts, the superior and inferior thyroid arteries were laid bare, and afterwards tied with the aid of a blunt crooked needle. They were afterwards transversely divided, and the remaining part of the tumour detached from the trachea, to which it strongly adhered. The wound resulting from this operation was near three inches in depth: it was outwardly bounded by the sterno-mastoideus muscle, and inwardly by the trachea and œsophagus; posteriorly by the carotid artery, and par vagum, which were exposed at the bottom of the wound. The extirpated tumour was five inches in circumference; and on examination was found to differ in no particular from acirrhous glands, except that in the centre there was a cartilaginous nucleus. The patient left the hospital, perfectly well, the 34th day after the operation. (See *Desault's Parisian Chirurgical Journal*, Vol. 2, p. 292—296.)

The extirpation of the thyroid gland is an operation extremely difficult, and certainly highly dangerous, when performed by an operator but moderately exercised in the practice of his profession. The number and size of the arteries necessary to divide, the proximity of the trachea, œsophagus, and carotid, near which the knife must necessarily pass, are the principal dangers which the operator should avoid. These are the circumstances which have deterred the majority of practitioners from performing it, and it must be allowed, that they are such as ought to intimidate every man, who is not endued

with correct anatomical knowledge, and the most undaunted coolness. Examples of this operation are very rare. The first time that Gooch undertook it, he was deterred from finishing it by the hemorrhage, and his patient died on the eighth day. The second time he succeeded better, but was incapable of securing the vessels, and succeeded in stopping the hemorrhage, which would otherwise have been mortal, by causing the parts to be compressed by the hand of an assistant for the space of eight days. (*Gooch's Med. and Chir. Obs.* p. 130; *Bell's System of Surgery*, vol. 5, p. 525; and *la Bib. Chir. de Richter*, t. 2, 4e partie, p. 128.)

A. F. Vogel and Theden have practised the same operation with the most complete success. All danger from the hemorrhage, or inconvenience arising from the discharge of blood, may be obviated by taking up the small vessels, tying them as fast as they are divided, and by discovering and tying the large vessels previous to their division. Other parts that cannot be wounded without danger, are to be avoided by dissecting slowly and a little at a time, and feeling with the finger every part, previously to its division with the bistoury.

TIC DOULOUREUX. This term is used to signify a disorder, the most prominent character of which consists in severe attacks of pain, affecting the nerves of the face; most frequently, the filaments of that branch of the fifth pair, which comes out of the infra-orbitary foramen; but, sometimes the other branches of the fifth pair, and occasionally the numerous filaments of the portio dura of the auditory nerve, which are distributed upon the face. The complaint is not continual, but occurs in violent paroxysms, which vary in duration in different instances. It is the *trismus dolorificus* of Sauvage; the *Faciei Morbus Nervorum Crucians* of Dr. S. Fothergill; and of that order of diseases, which Professor Chaussier has so aptly denominated *neuralgies*, (from *νευρον* a nerve, and *αλγος*, pain); for it should be known, that many other parts of the body are subject to a similar affection.

The first excellent description of the tic douloureux was published in the year 1776, by the late Dr. Fothergill. (See *Medical Observations and Inquiries*, Vol. 5.) It is not true, however, as is generally stated in modern medical works, that this gentleman was the first author, who noticed the complaint. This, indeed, is so far from being correct, that we even find an account of an operation done long ago for the relief of the disease by M. Louis (See No. 36 de la *Gazette Salulaire*, 1766); and this identical case actually became a subject of hot dispute between the physicians and surgeons of the French metropolis. (See a Thesis read to the Faculty of Medicine there, entitled

"*Utrum in pertinacibus capitis et faciei doloribus aliquid prodesse possit, sectio ramorum nervi quinti paris? Proponebat Viellart, 1768, conclusio negativa.*")

Tic douloureux conveniently admits of being divided into four species, called by the French *frontal*, *suborbital*, and *maxillary neuralgia*, and the *neuralgia of the facial nerve*.

In the frontal neuralgia, the pain usually begins in the situation of the supra-orbital foramen, extending at first along the branches and ramifications of the frontal nerve distributed to the soft parts upon the cranium, and afterwards shooting in the direction of the trunk of the nerve towards the bottom of the orbit. In a more advanced stage, the conjunctiva and all the surface of the eye participate in the effects of the disorder, and become affected with chronic inflammation, which is described as a particular species of ophthalmia. At length, the pain passes beyond the distribution of the branches of the frontal nerve, and affects all the corresponding side of the face and head. It seems as if it extended itself to the facial sub-orbital, maxillary, and even to the temporal and occipital nerves, through the communications naturally existing between the filaments of all those organs of sensation. Each paroxysm produces a spasmodic contraction of the eyelids, and a copious effusion of tears.

The sub-orbital neuralgia is first felt about the sub-orbital foramen. Its seat is probably in the nerve of this name, and the pain extends to the lower eyelid, the inner canthus of the eye, the muscles about the zygoma, the buccinator, cheek in general, ala of the nose, and the upper lip. At a later period, the pain appears to extend backward to the trunk of the nerve, and those branches which are given off in its passage through the sub-orbital canal. Hence, the pains are then experienced in the upper teeth, the zygomatic fossa, the palate, tongue, and within the cavity of the nose. As the disorder advances, it may extend, like all the other neuralgiae of the face, to all the same side of the head. During the paroxysms, when the disease is fully formed, an abundant salivation usually takes place. In general, the attendant toothach deceives the practitioner, who, in the belief that the pain arises from another cause, uselessly extracts several of the teeth.

The tic douloureux of the lower jaw, or maxillary neuralgia, is usually first felt about the situation of the anterior orifice of the canalis mentalis, and it extends to the lower lip, chin, neck, teeth, and temple. This form of the complaint is more uncommon, than the preceding; but, after it has prevailed some time, is equally remarkable for its intensity.

With respect to the neuralgia of the facial nerve, or portio dura of the auditory nerve, it is a case, which very soon cannot easily be distinguished from the other species of tic douloureux. The pains at an early period are no longer confined to the passage of the principal branches of this nerve between the parotid gland and ramus of the jaw. The numerous communications of the portio dura with the rest of the nerves of the face seem to facilitate the extension of the disease, so that the agony is soon felt over the whole side of the head. The original source of the disorder can only be detected by attentively considering the progress of the complaint in all its stages. (See *Delpach, Traité des Maladies Reputées Chirurgicales*, Tom. 3, Sect. 7, p. 214, &c.)

Tic douloureux may be known from rheumatism by the paroxysm being excited by the slightest touch; by the shortness of its duration, and the extreme violence of the pain. In acute rheumatism, also, there is fever, with redness, heat, and generally some degree of swelling; and in chronic rheumatism the pain is obtuse, long continued, and often increased at night; none of which symptoms characterize tic douloureux.

It may easily be distinguished from hemicrania by the pain exactly following the course of the branches of the affected nerve.

It is known from the toothach by the comparative shortness of the paroxysms; the quickness of their succession; the intervals of entire ease; the darting of the pain in the track of the particular nerve affected; the more superficial and lancinating kind of pain; and the convulsive twitchings, which sometimes accompany the complaint.

The causes of tic douloureux may be said to be in general unknown; but, there are a few instances recorded, which appeared to be the consequence of external violence, wounds, contusions, &c. A modern writer has related a very curious instance of a resembling disease in the arm, where the affection proceeded from the lodgment of a small bit of a bullet in the radial nerve. (*Denmark in Medico-Chir. Trans. Vol. 4, p. 48.*)

Stimulating embrocations, blisters, caustic issues, fomentations, leeches, frictions with mercurial ointment, (*Edinb. Med. and Surgical Journ. Vol. 3.*) electricity, opium in large doses, the arsenical solution, and a variety of antispasmodic medicines, are the principal means, which have been tried; but for the most part, they only afford partial and temporary relief. From some facts, recently published by Dr. Marcet, the extract of stramonium, in doses of $\frac{1}{2}$ and $\frac{1}{4}$ a grain thrice a day, seems to be sometimes capable of alleviating the dis-

pressing agony of the present disorder. (See *Medico-Chirurgical Trans.* Vol. 7, p. 75, &c.)

The operation of dividing the trunk of the affected nerve, and even of dissecting out a portion of it, so as to prevent all chance of a relapse from the reunion of the ends of the nerve, is the plan, which has sometimes been practised with permanent benefit. Thus, any one of the three branches of the fifth pair of nerves may be divided at the point, where it comes out upon the face. But, before having recourse to this means, the surgeon should be sure, that the particular nerve, which he is about to expose and divide, is really the principal seat of the disease; for, when all the nerves of the face generally are affected, or when the branches of the portio dura are especially concerned, there is little hope of success. In fact, it must be confessed, that the operation has had many failures and relapses, either from the cases not having been duly discriminated, or from the neglect to remove a portion of the exposed nerve. Richerand, Delpech, and most of the leading surgeons in France express their preference to the application of the moxa, or cautery, which they say proves more frequently successful, than the knife. This should be done directly over the apertures, from which the nerves emerge on the forehead, cheek, or chin, and Richerand asserts, that, by such treatment, the pains may always be cured, or at all events, rendered supportable. (*Nosographie Chir.* Tom. 2, p. 218, Edit. 4.) Delpech also affirms, that the section of the nerve very often fails, and that issues, and the repeated use of the cautery have been attended with the greatest success. (See *Précis des Mal. Chir.* T. 3, p. 213.) The disfigurement of the countenance by burning applications must, however, be very objectionable, and, as I think there is no positive evidence of the superiority of this method over the use of the knife, I consider what Richerand and Delpech have stated only as another instance of the extreme partiality of the French surgeons to the moxa and cauterization. Delpech confesses, however, that, when the pains seem to be the consequence of a ganglion, or thickening of a part of a nerve, the excision of such part is indispensable. There can be little doubt, that this would have been more proper, than amputation in Mr. Denmark's case, to which I have already referred.

There have been many examples of tic douloureux, which, after resisting all attempts to cure them, have been left to themselves, and, after a long time, spontaneously subsided. (*Delpech, Traité des Maladies Chir.* T. 3, p. 212—215.) This author has seen the operation of dividing the chief branches of the portio dura in front

of the parotid gland undertaken, and even a portion of the soft parts cut away; but, without any favourable consequences. (P. 218.)

I have already stated, that the nerves of the extremities are subject to affections very analogous to tic douloureux. The following instance related by Mr. Abernethy will be found interesting:

A lady became gradually affected with a painful state of the integuments under and adjoining to the inner edge of the nail of the ring-finger of the left hand. No injury to the part was remembered which could have brought on this disease. The pain occurred at irregular intervals, and was extremely severe during the time of its continuance, which was for a day or two, when it usually abated. Accidental slight injuries always produced great pain, and frequently brought on those paroxysms, which however occasionally occurred spontaneously, or without any evident exciting cause. In all these particulars, the disease correctly resembled the tic douloureux of the nerves of the face. As the pain increased, the disorder seemed to extend up the nerves of the arm. After the patient had endured this painful affliction for seven years, she submitted to have the skin, which was the original seat of the disorder, burned with caustic. This application gave her intense pain, and, on the healing of the wound, she found her sufferings rather augmented than diminished by this experiment. After four more years of suffering, she consulted Mr. Abernethy, when the circumstances of the case were such as to render an operation indispensably necessary. The pain of the part was intolerable, and it extended all up the nerves of the arm; and this general pain was so constant during the night, as to deprive the patient of rest. The muscles of the back of the neck were occasionally affected with spasms. The integuments of the affected arm were much hotter than those of the opposite side, and sometimes the temperature was so increased as to cause a burning sensation in them. Under these circumstances, Mr. Abernethy did not hesitate to divide the nerve of the finger, from which all this disorder seemed to originate. He laid it bare by a longitudinal incision of about three quarters of an inch in length, from the second joint of the finger, and divided it opposite to that joint, by a curved sharp-pointed bistoury, which was conveyed under it. He then took hold of the nerve with a pair of forceps, and reflecting it downwards, removed a portion of it, half an inch in length, that the possibility of a quick reunion might be prevented. The wound was brought together by sticking plaster, and it united by adhesion; but, the upper part of the wound, opposite to the upper end of the

nerve, became slightly inflamed, and was very painful. However, the appearance of inflammation gradually went off in the course of three weeks. After the operation, Mr. Abernethy pinched the originally affected integuments sharply with his nails, without causing any sensation; but if, in so doing, he moved the finger, then pain was felt. Mr. Abernethy found it difficult to convince the patient, that the skin at that part was actually devoid of sensation, for she still continued to feel similar sensations to those, which formerly occurred, though in a much diminished degree: but she became gradually as perfectly convinced as any medical man could be, that these sensations arose from the irritated state of the end of the nerve, above the place where it was divided. The painful affection of the nerves of the arm still continued, though considerably lessened in violence; however it was sufficiently severe to make the patient apprehend, that little permanent benefit would arise from the operation. This pain continued occasionally about four months with varying degrees of severity, but the temperature of the skin was not hotter than that of the opposite side, as it had been before the operation. At the expiration of three months, the patient ascertained, that the integuments at the end of the finger actually felt when any thing was applied to them, and this proved a new source of alarm. Mr. Abernethy adds, that more than nine months have now elapsed, since the performance of the operation, and the general pains in the nerves have become very trivial; but, the sensation of the integuments at the end of the finger, has during that time gradually increased, and the skin has now its natural sensibility, so as accurately to distinguish the tangible properties of any body applied to it. If also the originally affected part be slightly compressed, painful sensations resembling those which formerly occurred take place. (*Abernethy's Surgical Works*, Vol. 2, p. 203.)

Mr. Lawrence once mentioned to me a case resembling the former, and which was the consequence of a wound of the finger. This gentleman also cut down to the nerve, and removed a portion of it, with permanent success.

Consult particularly *Dr. Fothergill's Paper* in vol. 5, of the *Medical Observations and Inquiries*. *Dr. Haighton's Obs. in the Medical Records and Researches*. *Darwin's Zoonomia*. *Abernethy's Surgical Works*, Vol. 2, p. 203, &c. *Richerand's Nosographie Chirurgicale*, T. 2, p. 216, &c. Edit. 4. *Delpech Précis des Maladies Chir.* T. 3, p. 206 &c. *Dr. S. Fothergill's Systematic Account of Tic Douloureux*, 1804. *Medico-Chir. Trans.* Vol. 4, p. 48, Vol. 7, P. 575, &c.

TINCTURA CANTHARIDIS. (*lyttae*.) Surgeons sometimes employ this medicine, in cases of gleet, and incontinence of

urine, arising from a want of proper action in the sphincter vesicæ muscle. The usual dose is from ten to forty or sixty drops, twice or thrice a day; but its effects should be vigilantly attended to; for, it is apt to occasion dangerous inflammations of the urinary organs, violent stranguaries, and retentions of urine.

Tincture of cantharides has occasionally been used as an ingredient in various liniments, when the object has been to stimulate the skin, and rouse the action of the nerves and absorbents, as in certain cases of ptosis, paralysis, &c.

TINCTURA FERRI MURIATI. The writer of the *Pharmacopœia Chirurgica* remarks, that the tinctura ferri muriati has sometimes been exhibited "for gleet; but a more important use has been assigned it by Mr. Cline, who orders it in dysuria, when a consequence of stricture, in the dose of ten drops every twenty or thirty minutes. This relaxes the spasm, through which the retention is occasioned, by a mode of operation not easily explained.

"Mr. Justamond's liquid for external use in cancers, and which the original inventor called his *panacea anticancroza*, partook considerably of the nature of this tincture, which, indeed, with an equal quantity of spirit of wine, was sometimes substituted for it.

"Lastly, it is remarkably efficacious in destroying venereal or other warts, either used alone, or diluted with a small proportion of water."

TINCTURA THEBAICA. *R.* *Opii purificati* ℥ij. *Cinnamomi*, *Caryophyllorum*, sing. ℥j. *Vini, albi lib.* j. These are to be macerated, without heat, for a week, and then filtered.

This was one of the formulæ of the old London Dispensatory, and though the tinctura opii is now substituted for it in that work, yet, in one particular surgical case, it is found that the tinctura thebaica cannot be superseded by the other preparation, without great disadvantage to the patient: I allude to inflammation of the eyes. The late Mr. Ware found the tinctura thebaica, in this instance, eminently serviceable. His plan was to put one drop of it into the eye, once or twice a day, according as the symptoms were more or less violent. When first applied, it causes a sharp pain, accompanied with a copious flow of tears, which continues a few minutes, and gradually abates; after which a greater and remarkable degree of ease generally succeeds. This gentleman observes, that "the inflammation is often visibly abated by only one application of this tincture; and many bad cases have been completely cured by it in less than a fortnight, after every other kind of remedy had been used for weeks, and sometimes months, without any success. But

this speedy good effect is not to be expected in all cases indiscriminately. In some, the amendment is more slow and gradual, requiring the tincture to be made use of for a much longer time; and a few instances have occurred, in which no relief at all was obtained from its first application. In cases of the latter kind, in which the complaint is generally recent, the eyes appear shining and glossy, and feel exquisite pain from the rays of light. However, notwithstanding these symptoms, the application is sometimes found to succeed; and whether it will or not, can only be determined by making the trial; which is attended with no other inconvenience than the momentary pain it gives. When it is found to produce no good effect, the use of it must be suspended, until evacuations, and other proper means, have diminished the excessive irritation; after which, it may again be applied, and bids equally fair for success, as in those instances, in which it never disagreed.

If two or three drops of the thebaic tincture are applied at once to the globe of the eye, the pain they occasion will be considerably greater than if they are placed in the inner angle of the eyelids, and made to glide gradually on the eye, by gently drawing down the lower lid. At the same time that this latter mode of applying the tincture is much less painful than the former, Mr. Ware has found, in a great variety of cases, that it is equally beneficial. (See *Ware's Remarks on Ophthalmia*, &c. his *Additional Remarks* on the same subject; and the article *Ophthalmia* in this Dictionary, at which part of the book, the particular cases, in which the application can be judiciously made, are pointed out.) The reader should be well apprised, that the tinctura thebaica cannot be made indiscriminate use of for all inflammations of the eyes, without doing serious mischief in many instances.

TINEA CAPITIS, or **PORRIGO**, (called also *Ringworm of the Scalp*; *Scald-head*, &c.) is, according to Dr. Bateman's excellent account of the subject, a contagious disease, principally characterized by an eruption of the pustules denominated *favi* and *achores*. The *achor* is defined to be a small acuminate pustule, containing a straw-coloured matter, which has the appearance and nearly the consistence of honey, and is succeeded by a thin brown, or yellowish scab. The *favus* is larger, flatter, and not acuminate, and contains a more viscid matter; its base, which is often irregular, is slightly inflamed; and it is succeeded by a yellow, semi-transparent, and sometimes cellular scab, like a honey-comb; whence, it has obtained its name. (See *Bateman's Synopsis of Cutaneous Diseases*, p. xxiv and 159, Edit. 3.)

This intelligent physician has noticed

six species of porrigo, of which my limits will allow me to give only a very abridged description.

1. The *Porrigo larvalis*, or *crusta lactea* of authors, begins with an eruption of numerous minute whitish *achores*, upon a red surface. These pustules soon break, and discharge a viscid fluid, which concretes into thin yellowish, or greenish scabs. The disease increases in extent, and the scabs become thicker and larger, until the forehead, cheeks, and even the whole face, excepting the eyelids and nose, become enveloped, as it were, in a mask, whence the epithet *larvalis*. Small patches of the disease sometimes appear about the neck and breast, and on the extremities; and the ears and scalp are usually affected in the progress of the case. The infant suffers more or less from the itching and irritation. When the discharge is copious and acrid, Dr. Bateman recommends the part to be washed two, or three times a day with tepid milk and water, and the application of the unguentum zinci alone, or mixed with the saturnine cerate. The latter, he says, will be useful for the relief of the excoriation, left after the cessation of the discharge. Small doses of the submuriate of mercury, either alone, or in combination with a testaceous powder, will also expedite the cure. If the bowels are very irritable, the hydrargyrus cum creta, or the cinereous oxide, may be exhibited, instead of the calomel. When the health is good, soda, precipitated sulphur, and the testacea, will lessen the local inflammation and discharge.

When the irritation is removed, and the crusts are dry and falling off, the unguentum hydrarg. nitrat. much diluted, may be used, and the decoction of bark, or the vinum ferri prescribed.

2. *Porrigo furfurans* begins with an eruption of small *achores*: The excoriation is slight, and the discharge, which is not abundant, soon concretes, and falls off in innumerable thin laminated scabs. At irregular periods, fresh pustules arise, and follow the course of the preceding. The complaint is confined to the scalp, which is affected with itching and soreness; and the hair, which partly falls off, becomes thin, less strong, and sometimes of a lighter colour, than natural. This species of porrigo occurs principally in adults, and it is sometimes attended with swelling of the glands in the neck. Dr. Bateman observes that the treatment requires the hair to be closely cut off the scalp. The branny scabs are then to be gently washed away with some mild soap and water twice a day; and an oil silk cap should be worn. In the beginning, when the surface is moist, tender, and inflamed, the zinc ointment, or one made with ℥ij. of the cocculus indicus and ℥j. of lard. Afterwards, when the scalp is dry and free from irritation, it

may be washed with common soft soap and water; or with a mixture of equal parts of soft soap and unguentum sulphuris. Then the unguentum hydrargyri nitrati, the ung. hydrarg. nitrico oxydi, the tar and sulphur ointments, or the ung. acidi nitrosi of the Edinb. Pharm. may be employed. These last stimulant applications, however, must be left off, if the inflammation and discharge return.

3. *Porrigo lupinosa* is characterized according to Dr. Bateman by dry, circular, yellowish white scabs, set deeply in the skin, with elevated edges, and a central depression, and somewhat resembling on the whole, the seeds of lupines. These scabs are formed upon separate clusters of *achores*, and attain on the scalp the size of a sixpence; but, when on the extremities, they are not more, than two lines in diameter.

In the treatment of the *porrigo lupinosa*, the scabs are first to be gently washed off with some soap and water, and the scalp is to be shaved, if it be the part affected. When the scabs are difficult of removal, the liquor potassæ, or a weak lotion of muriatic acid may be used for loosening them. Then the ointment of *cocculus indicus* is to be applied to the red cuticle, and afterwards any of the more stimulant ointments above enumerated.

4. *Porrigo Scutulata*, or ring-worm of the Scalp, as Dr. Bateman has observed, makes its appearance in separate patches, of an irregularly circular shape, upon the scalp, forehead, and neck. It commences with clusters of small, light yellow pustules, which soon break, and form thin scabs, which, if neglected, become thick and hard. If the scabs are removed, however, the surface underneath is left red and shining, but, studded with slightly elevated points, or pustules. When the disorder is neglected, the patches become confluent, and the whole head affected. Where the disease is situated, the hair becomes lighter in its colour, it falls off, and its roots are destroyed. The *porrigo scutulata* generally occurs in children three or four years old and upwards, and frequently proves exceedingly obstinate. According to Dr. Bateman, it seems to originate spontaneously in children of feeble and flabby habit, and who are ill-fed, uncleanly, and not sufficiently exercised; but, he thinks that it is chiefly propagated by contagion, i. e. by the actual conveyance of the matter from the diseased to the healthy, as may happen in the frequent contact of the heads of children, the use of the same towels, combs, caps, and hats.

While the patches are inflamed and irritable, it is necessary to limit the local applications to washing the parts with warm water. Even shaving the scalp, which must be repeated at intervals of eight or ten days, produces a temporary irritation.

Nothing but a light linen cap is now to be worn, and it must be often changed.

The disease afterwards forms dry scabs, and becomes for a time less irritable; but a fresh eruption of *achores* soon follows, and the inflammation and redness return.

In the inflamed states, Dr. Bateman recommends the use of ointments, made either with the *cocculus indicus*, submuriate of mercury, oxide of zinc, superacetate of lead, opium, or tobacco; or else the infusion of poppy heads, or tobacco. Where there is an acrimonious discharge, Dr. Bateman prescribes the zinc, or saturnine ointments, the ung. hydrarg. præcip. calomel ointment, or a lotion of lime water and calomel.

In the less irritable stages, the ung. hydrarg. præcip. the ung. hydrarg. nitrico oxydi, and especially the ung. hydrarg. nitrati. are often effectual remedies. So are the ointments of sulphur, tar, hellebore, and turpentine, and lotions of the sulphates of zinc and copper, the oxymuriate of mercury. I have often seen a solution of ʒj. of the sulphuret of potassa in a pint of lime water, succeed when most other applications had failed. In the very dry and inert state of the patches, Dr. Bateman has seen the disease removed by a lotion, containing from three to six grains of the nitrate of silver in an ounce of distilled water. The application of the diluted mineral acids, or of a blister, has also been known to put a permanent stoppage to the morbid action.

In general, no local application agrees well, if long continued, and it is necessary to have several, which must be alternately employed.

The cure may often be expedited by cinchona, chalybeate, and alterative medicines; and attention must be paid to the patient's diet, exercise, &c.

5. *Porrigo Decalvans* consists in bald patches, surrounded by hair, which is as thick as usual. It is not known, whether any eruption of minute *achores* actually precedes the detachment of the hair.

Dr. Bateman remarks, that if the scalp is regularly shaved, and some stimulating liniment be applied to it, this obstinate affection may at length be overcome, and the hair will regain its usual strength and colour. Two drams of oil of mace in three or four ounces of alcohol, are said to make an excellent liniment.

6. *Porrigo favosa* consists of an eruption of the large, soft, straw-coloured flattened pustules, denominated *favi*, which may occur on any part of the body; but most commonly spread from the scalp, especially behind the ears, to the face, or from the lips and chin to the scalp. They are attended with considerable itching, and are most frequently seen in children from six months to four years of age, though adults

are also often affected. The pustules pour out a viscid matter, which concretes into greenish or yellowish semi-transparent scabs. When the hair and moist scabs are matted together, pediculi are often generated in great numbers, and aggravate the itching and irritation. If the disease be allowed to increase, the scabs are thickened into irregular masses, not unlike honey-comb; and considerable ulcerations sometimes form, especially when the heel and toes, or other parts of the lower extremities are affected. The ulcerating blotches are generally soon followed by irritation and swelling of the lymphatic glands, which sometimes slowly suppurate. The contact of the discharge inoculates the disease; thus, in young children the breast is inoculated by the chin; and the arm and breast of the nurse may be infected in the same way; though adults do not take the complaint so quickly as children.

The porrigo favosa requires the same alteratives internally, as the porrigo larvalis. The diet should consist of milk, puddings, and a little plain animal food. When the habit is bad, and the glands swelled, bark, chalybeates, and a solution of the muriate of barytes, are proper.

As local applications, Dr. Bateman prefers the unguentum zinci, or the ung. hydrarg. præcip. mixed with this or the saturnine ointment, especially, when the discharge is copious. He also speaks favourably of the ung. hydrarg. nitrat. the strength of which is to be diminished by an addition of simple cerate, according to the degree of irritation present.

For the preceding particulars I am indebted to Dr. Bateman's valuable Synopsis of Cutaneous Diseases, where the reader, desirous of additional information, respecting porrigo, will be amply gratified.

TOBACCO is used for promoting the reduction of strangulated hernia. For this purpose it is employed either in the form of a fluid glyster, or of smoke, which latter is introduced up the rectum by means of an apparatus. Excepting the operation, the power of tobacco, particularly, when assisted with the topical application of cold to the tumour, is most to be depended upon in bringing about a return of the protruded viscera. (See *Hernia*, and also *Enema*.) It has also been tried in tetanus, but without success; and Mr. Earle has found tobacco clysters very efficacious in certain cases of retention of urine. See *Tetanus*, and *Urine, Retention of*.

TONGUE, DISEASES OF. This part is subject to various diseases, as ulcers, tumours, and such enlargements as sometimes put the patient into imminent danger.

Carious teeth, with points and inequalities, occasioning incessant irritation, are the most frequent cause of ulcer-

ations of the tongue. The sores, thus produced, often resist every kind of remedy, and ignorance of the cause sometimes leads the practitioner to consider them as incurable; whereas, a cure might easily be effected by extracting the carious tooth, or simply filing off its sharp irregularities and pointed parts. This advice is exceedingly ancient, being mentioned even by Celsus.

The glandular papillæ which are situated on the dorsum, or upper surface of the tongue, are naturally formed with a narrow base, and a broad termination or head, like a mushroom. They are capable of becoming considerably enlarged, so as to form preternatural tumours which may be very improperly mistaken for cancerous excrescences.

A young man, eighteen years of age, had on the middle of his tongue a circumscribed tumour, about as large as a middle-sized nutmeg. M. Louis, who was consulted, perceived that the swelling was only of a fungous nature, and he tied its base with a ligature, with the noose of which he contracted the diameter of the pedicle, while, with the ends, he kept down the tongue. Then, with one stroke of a pair of curved scissors, he cut off the tubercle. M. Louis afterwards applied caustic, with the requisite precautions, to the base of the tumour, and the patient got perfectly well in five or six days. (*Mémoires sur les Maladies de la Langue in Mémoires de l'Acad. de Chirurgie, Tom. 5.*)

Morgagni speaks of similar tubercles; but he had never advised their extirpation, not even when they had become hard and scirrhus; for, if he had not deemed the operation impracticable, he would not have had any confidence in the skill of the surgeons employed. (*De Causis et Sedibus Morborum.*)

The tongue is occasionally affected with a true cancerous disease; one of the most afflicting cases, indeed, to which mankind are exposed. M. Louis saw a lady, who had an ulcerated cancerous tubercle on the left edge of the tongue. The little swelling was circumscribed; its size did not exceed that of a filbert; the pains were lancinating; the sore had penetrated deeply; and its tuberculated edges were affected with a scirrhus hardness. Extirpation of the disease seemed to present the only chance of freeing the patient from the terrible disorder; but, she refused to accede to any thing but palliative plans, and she died in the course of a few months.

Forestus makes mention of four women, who were attacked with cancer of their tongues, and died from the ravages of the disease, and hemorrhage. In the writings of Fabricius Hildanus, there is a description of the origin and progress of a cancerous tubercle on a young man's tongue,

who had a most intolerable fetor of the breath, and died, suffering the most excruciating pains. The same author informs us of another case, exhibiting the good effects of sedative remedies in palliating a cancerous ulcer of the tongue, and the fatal consequences of an opposite line of conduct. In authors, many other examples, of the same kind, are to be met with.

Surgery, however, is not destitute of resources against diseases of so formidable a nature. The following case will serve to shew, what benefit may be effected by this useful profession, when not exercised by men of too timorous a character.

An elderly woman had an ulcerated hardness on her tongue. It had been several times cut away, and as repeatedly returned. Ruysch was called in to a consultation with one of the surgeons, who was attending the patient, and who had already extended his incisions very deeply for the removal of the disease. The result of their deliberations was another attempt to extirpate the tumour, and they also determined, that after it had been cut away, the actual cautery should be freely applied, with a view of destroying the roots of the fungus. The patient consented to the plan, and bore the operations with great fortitude. The tongue was taken hold of with a cloth, and Pierre Le Memnonite, a surgeon of eminence, removed the disease with a curved bistoury. The inside of the mouth was then protected with wet cloths, and the actual cautery applied, several times to the wound in the tongue. The pain was appeased, and the separation of the eschar promoted by emollient gargles. The place soon healed, with the aid of what were called vulnerary decoctions, containing honey of roses, and the tincture of myrrh and aloes.

It is much easier to cut off a complete portion of the tongue, through all its diameter, than to remove a cancerous ulceration, situated on one of its edges.

In both cases, there is a good deal of difficulty in fixing the part, for it is so very moveable, that it is not easy to keep it in a steady position. M. Louis recommended, for this purpose, the employment of forceps, with blades which terminate in hook-like extremities. With this instrument, the part of the tongue to be amputated can be kept from slipping away from the operator.

Cruel as the operation of removing the tongue may appear, the surgeon should not hesitate to perform it, whenever the disease has made a certain progress, and is decidedly of a cancerous nature.

It should be noticed, however, that very malignant ulcers on the tongue have sometimes been cured by milder means. Sores

of this description are reported to have yielded to the repeated application of leeches under the tongue, after a vast number of other remedies had been tried in vain. In the *Encyclopédie Méthodique*, *Art. Langue*, there is an account of a very alarming affection of the tongue, (reputed to be cancerous, though this may be doubted,) which got completely well under a very simple plan of treatment. A woman, thirty-five years of age, subject to cutaneous diseases, and ill-conditioned ulcers, complained, for seven or eight months, of little swellings, accompanied with heat and pain, which made their appearance on the edge, and towards the apex, of the tongue. At length, the part affected began to swell, grow hard, and cause lancinating pains. Its surface became irregular and rough; and all the side of the tongue was considerably swelled. The patient could not put her tongue out of her mouth, nor swallow any thing except liquids; and her breath was intolerably fetid. Various sedative remedies had been employed without success. Cicuta had been used as a topical application; it had been exhibited internally in large doses; the patient had taken, for a long while, the oxymuriate of mercury; but nothing proved of any avail. At length, the patient was so tired of trying the effect of medicines and applications, that she gave them up entirely; and contented herself with trying the experiment of keeping some honey continually in her mouth. As this method seemed to give her some ease, she was prevailed upon to persist in it, and, in this way, the pains were gradually appeased; the swelling was diminished, and, at the end of two or three months, the woman got quite well, except that an indurated cicatrix remained on the part affected, and considerably obstructed the extension of the tongue on that side.

On this case, however, it might be remarked, that the retardation of the cure seems also ascribable to the injury of the health produced by the hemlock, mercury, &c. and that the amendment, following their discontinuance, might arise from the consequent improvement of the patient's health.

Many writers have confirmed the fact, that very inveterate diseases of the tongue are sometimes cured by hemlock. In the work, last cited, is mentioned an instance of a very unhealthy-looking ulcer, near the apex of the tongue, attended with a considerable thickening of the part, and of some duration, which was cured by giving large doses of cicuta.

However, notwithstanding many facts of this kind on record, medicines should not be tried too long, that is to say, so as to let the disease attain a condition, in

which it will no longer admit of being cut away. When the disease makes progress, the knife should be employed, before it is too late.

When any part of the tongue is to be amputated, the surgeon is to be prepared for putting a stop to the hemorrhage. Authors very properly recommend the chief vessels to be tied, if possible; but, when this cannot be accomplished, they advise the employment of astringent gargles, such as a strong solution of alum, distilled vinegar, or diluted sulphuric acid. When these methods fail, the continental surgeons recommend the actual cautery as the only resource. Some surgeons, however, impressed with the horror of red-hot irons, might think it better to tie the trunks of the lingual arteries, as they pass over the os hyoides. A patient should undoubtedly never be suffered to die of bleeding, and some bold step ought certainly to be taken; but, I cannot presume to decide, which of the two latter measures is the best. Perhaps, by a practitioner, well acquainted with anatomy, the last one should be preferred.

The whole of the tongue sometimes inflames, and becomes considerably enlarged, either spontaneously, and without any apparent cause, or in consequence of some other disease; or else from some particular irritation; such as that of mercury, or some poisonous substance. Slegel, a German physician, who was at Paris about the middle of the 17th century, saw a patient in a salivation, whose tongue became so enormously enlarged, that the mouth could not contain it. Pimprenelle, an eminent surgeon of that time, was sent for, and finding that all trials to relieve the affection were in vain, amputated one half of the tongue, with a view of preventing its mortification. When the wound was healed, it is said, that the patient could articulate as well as before. M. Louis, from whom this fact is quoted, very justly remarks, that the measure resorted to by M. Pimprenelle was an exceedingly violent one; for he has often seen urgent symptoms occasioned, during a salivation, by a rapid and enormous swelling of the tongue, very quickly yield to bleedings, purgative glysters, change of air, and leaving off mercury. Two or three facts, confirming this statement, have fallen under my notice since the last edition of this Dictionary.

Trincavellius mentions two women, who had considerable enlargements of their tongues. One of these patients, who was young, had been rubbed with mercurial ointment even on her head; and the other, who was about fifty years old, had her tongue attacked with the ravages of the small-pox. The excessive swelling of the tongue, in both these instances,

terminated in resolution, and a separation of its outward membrane.

When the urgency is such, that an immediate diminution of the swelling becomes necessary for the relief of the symptoms, nothing, it is said, is attended with so much success, as at once making one or two deep incisions along the tongue. This, it is added, is particularly proved by the cases, inserted by M. de la Malle, in the fifth volume, 4to. of the *Mem. de l'Acad. de Chirurgie*, and by some others, related by M. Louis in the paper above cited. Such cases are extremely interesting, and seem to merit an insertion in this Dictionary.

A man, who was recovering from a bad fever, was suddenly attacked with a pain in his tongue, followed by a swelling equally large and rapid in its formation. In less than five hours, the part became thrice as large, as it is in its natural state and, in this space of time, M. de la Malle, who had been consulted, had bled the patient successively in his arm, neck, and foot. The man felt very acute pain; his skin was excessively hot; his face was swelled; his pulse was hard and contracted; and his look wild. He could hardly breathe; the tongue filled all the cavity of the mouth, and protruded out between the lips. In this very urgent case, the surgeon had recourse to no other expedient, than keeping the mouth a little more open than it was made to be by the swelling of the tongue, and making with a knife three parallel incisions along this organ, one along its middle, and the other two between the one in the centre and the edges of the part affected. The cuts extended through two-thirds of the preternatural swelling, and had all the good effect which could possibly be desired. There was a great deal of hemorrhage, and the enlargement of the tongue subsided so much, that, an hour after the operation, the patient was able to speak. The next day, the incisions had the appearance of being only superficial scarifications, and the tongue was in its natural state. In short, the incisions healed in a few days, the patient having merely made use of a simple gargle.

M. de la Malle quotes several other cases, all of which tend to shew the success, which he has met with in applying this practice to other similar cases. He confirms his own sentiments, by quoting the testimony of some authors, antecedent to him, who have recommended the method; and, in particular, he cites a case, in which Job à Meckren, an eminent Dutch surgeon in the middle of the seventeenth century, adopted this practice, in a case, where the tongue, together with the tonsils and palate, became spontaneously affected with a sudden and dangerous degree of swelling.

It may be concluded from the preceding observations, that making incisions into the tongue would have saved numerous patients, who have been suffocated, in consequence of enormous enlargements of this organ. In the small-pox, the tongue sometimes becomes immensely swelled; and, it is more than probable, that, in many instances, the employment of the above method would have afforded great relief to patients, whom the disease has been known to have entirely bereaved of the power of swallowing. (See *Mémoire sur les Maladies de la Langue, dans les Mémoires de l'Acad. de Chirurgie, Tom. 5. Mem. de M. Malle; same Work. Encyclopédie Méthodique, Partie Chirurgicale, Art. Langue.*)

TONSILS. (dim. of *tolæ*, the kernels.) *Tonsillæ. Amygdalæ.* The tonsils, like all the other parts at the back of the mouth, are subject to different kinds of swelling, which vary as much in their nature as their consequences. Some are rapid in their progress, and these are frequently observed to affect persons of, what is termed, a sanguineous temperament. They are also prone to attack young people, and such as labour hard, and they have all the essential characters of inflammation.

Other swellings of the tonsils are slower in their progress, occur in damp cold weather, and in indolent, and, what the old physicians used to call, phlegmatic constitutions.

Lastly, another kind of enlargement of the tonsils, which is usually contagious, readily falls into a sloughing, gangrenous state, sometimes extends to the neighbouring parts, and too often proves fatal. Hence, the various species of angina have been named by some writers inflammatory, catarrhal, and gangrenous. The two first kinds frequently terminate in resolution; but, sometimes, the affected tonsils afterwards assume a scirrhus hardness, obstruct respiration and deglutition, so that it becomes indispensably necessary, either to extirpate the diseased parts, with the ligature, or the knife.

The cutting away of enlarged tonsils was an operation, which was performed by the ancients, and, in different ways. Sometimes, they tore with their fingers the membrane covering the tonsil, and then pulled this part out of the situation, which it occupies between the two pillars of the velum pendulum palati. In other instances, in which they experienced too much resistance, they seized the diseased tonsil with a kind of hook, and then cut it away with a bistoury, which, Paulus Ægineta informs us, was concave on the side towards the tongue.

The moderns, who, for a long while, were timid in the employment of both these methods, adopted plans of a more

cruel description. The actual cautery was proposed, and some partial success, which followed its use, at once established its reputation. Caustics were afterwards employed, instead of actual fire; but, the inconvenience of not being able to limit their action, and the hazard of their falling down the œsophagus, soon caused them to be relinquished by all rational practitioners. Then the operation of cutting away the tonsils was revived, and it was performed, sometimes in the manner of the old surgeons, sometimes with various kinds of curved scissors, or knives. Instead of the simple tenaculum used by the ancients, a sort of double one came into fashion. Every practitioner seemed to regulate the choice of his instruments, by his own ingenuity; and an operation, which was capable of being done at once, became complicated by being divided into several processes.

Bichat describes the following plan, as the common one practised at the present day.—The patient being conveniently seated, the surgeon is to open the mouth very wide, and depress the tongue with any flat instrument, which is afterwards to be committed to the care of an assistant. The operator is then to take hold of the diseased tonsil with a tenaculum, and with a common scalpel, having the back half of its blade covered with rag, he now removes as much of the tonsil, as ought to be taken away. In common cases, it is deemed sufficient to cut on a level with the pillars of the velum pendulum palati. If any other portion should require removal, this should next be performed. The operation being finished, the patient is frequently to wash his mouth with proper gargles.

The preceding plan seems a very simple and easy one, and was, for a long while adopted by Desault. It is said, however, to be liable to one objection, which is, that, when the end of the knife is conveyed far into the mouth, it may do mischief, not (as has been alleged) to the internal carotid artery, the backward situation of which completely keeps it out of all danger of being wounded, but to the membranous covering of the palate, in a place not corresponding to the tonsils. Desault thought this objection was the more forcible, as when the hook is introduced into the tonsil, the danger of the above mischief is considerably increased by a general spasm, which seems to affect every part of the mouth. Hence, this eminent surgeon used to employ, for cutting away diseased tonsils, an instrument, which was first invented for dividing cysts of the bladder. The contrivance consisted of a sharp-edged blade, which was included in a silver sheath. The latter had at its extremity a kind of notch, in

which the gland, which was to be extirpated, was received. The rest of the instruments were similar to those used in the operation above described. Desault used to proceed, as follows :

1. The patient being seated on a high chair, with his head supported on an assistant's breast, the surgeon is to make him open his mouth very wide, and the lower jaw is to be kept thus depressed, by any solid body placed between the teeth, and held there by an assistant.

2. The tongue is to be kept down with a broad spatula.

3. The surgeon is next to take hold of the tonsil with a double hook, with which he is to raise and draw it a little towards him. He is then to take the above cystitome, and put the tonsil in the notch, on a level with the place, where the incision is intended to be made.

4. When the portion, which is to be cut off, is engaged in the notch, the operator is to draw the part towards him, so as to stretch it, and press the instrument against it from below upward. The blade being next pushed across the notch, the necessary section is accomplished. When the division is not complete, which is particularly liable to happen, when the diseased gland is of considerable magnitude, the blade is to be drawn back, and the section completed by applying the instrument to the wound, which it has already made. Even a third application may possibly become requisite on some occasions.

5. The patient is to be directed to wash his mouth. Bichat states, that this plan of operating, adopted by Desault, is equally simple and easy as the method above related, with the advantage of being safer. Such is the construction of the blade of the instrument, that when it slides across the notch, it presses against, and steadily fixes the parts, which are to be divided; an advantage which neither the knife nor scissors have, before the action of which the parts are quite moveable. Hence, there is difficulty in cutting them. When the introduction of the instrument from above downward, is difficult, it is better to withdraw it; and, after turning the notch in the opposite direction, pass it from below upward. In general, however, the first of these methods is preferable, because the gland, when half cut through, cannot now fall back and obstruct the rima glottidis, so as to bring on danger of a sudden suffocation; a circumstance which Wiseman and Moscati have seen happen. With a view of preventing this occurrence, M. Louis recommended the common scalpel to be used, with its edge directed upward, as has been advised for the above instrument; which latter contrivance however, being, according to Bichat's account, more easy and

safe, merits the preference. Besides the advantage of fixing the soft parts, which are to be cut, it has that of not contusing them, like most other instruments of this nature, as, for instance, scissors. The oblique disposition of its blade makes it divide parts, in the manner of a saw.

The above contrivance, as Bichat allows, is certainly increasing the number of surgical instruments; a thing, which all the best modern surgeons endeavour to avoid. But, as this author remarks, this instrument is not exclusively applicable to any particular operation. It may be employed for cutting away the tonsils and uvula; dividing membranous fræna in the rectum, vagina, and bladder; amputating fungous excrescences, polypi of the nose, (if this mode of extirpating them were preferred) and various tumours in general, which are deeply situated in different cavities of the body, where instruments introduced unguardedly might injure parts which should be avoided, or where the base of the tumour should be steadily fixed, when its division is to be accomplished. The latter object cannot safely be effected by scissors. When the base of the tumour is too large to be received in the notch, one part is first to be divided, and then another, till its whole thickness is cut through.

The ligature, as a means of extirpating enlarged tonsils, is, in general, only proper for timid patients, who will not have the knife employed, or whose fears are such as would baffle the operation with a cutting instrument. Tying the tonsils is more tedious, and not at all less painful, than cutting them away, and always creates a vast deal more irritation. Moscati having once adopted this plan, very severe pain and inflammation ensued; the difficulty of swallowing and breathing compelled him to amputate the tumour at the place where the ligature was applied, and all the bad symptoms immediately ceased. Besides, when the ligature is used, the oozing of blood cannot take place from the ends of the cut vessels, and which tends so much to diminish the inflammation. The base of the swelling is also commonly broader than its upper part, and does not admit of being properly surrounded with a ligature. And, when it has a narrow base, it can then be so easily removed with a cutting instrument, or with Desault's instrument, and with so little pain, that one of the last modes is always preferable.

The ligature, however, has had its advocates. Heister recommends it, in certain cases; Sharp praises it; and others approve its use, and the plans of employing it have been as various as the inventive genius of the different partisans of the practice. Some make use of Levret's double cannula, which is furnished with

a silver wire noose, in which the tumour is to be engaged. By twisting the instrument, the diseased part becomes constricted; and this plan being repeated every day, the circulation is intercepted, and the gland mortifies, and sloughs away. Some, after putting the noose of a ligature over a kind of tenaculum, hook hold of the tonsil, push the ligature over the enlarged gland, which they tie, without having any means of increasing the constriction every day. Some employ Belloque's instrument for putting the ligature over the tonsil. Others require no instrument whatever for the purpose, and accomplish the business with their fingers.

Passing over a more ample historical detail, we need only observe, that two inconveniences generally attend all the above plans. Some of them do not admit of the constriction being afterwards increased, and, therefore, are apt to prove insufficient. Indeed, this is usually the case; and it becomes necessary to apply another ligature. Others of the above methods, free from this objection, are attended with the inconvenience of leaving in the mouth too large a body, which is very annoying. The repeated twisting of the wire, also, sometimes makes it break, and renders another operation indispensable, which is much more painful than the first one.

In order to obviate these inconveniences, Desault employed an instrument, which the French call *un serre-nœud*, which is an exceedingly simple thing, being, in fact, nothing more than a long, narrow, round piece of silver, terminating at one end in a little ring, or hole, and, at the other, in a kind of groove or notch. Desault sometimes employed the same instrument for tying nasal polypi, and tumours in the vagina, and rectum.

The following was this celebrated surgeon's method of extirpating the tonsils with a ligature.

1. The patient is to be seated on a high chair, with his head held back, on an assistant's breast; his mouth is to be opened very wide, his tongue depressed, and the diseased tonsil taken hold of with a double hook.

2. The surgeon takes the *serre-nœud*, in which a ligature has been passed, so as to form a noose. The noose is to be put over the handle of the hook, which is to be committed to the charge of an assistant, and the noose then pushed over the tonsil, so as to embrace it completely.

3. The surgeon is now to draw the ligature strongly towards him, and push forward the *serre-nœud*, so as to produce the requisite constriction of the tumour. In general, the ligature should not be made very tight the first day.

4. When the constriction is such as it

ought to be, the double-hook is to be withdrawn, and the ligature twisted round the notch, at the outward end of the instrument.

5. The next day, the gland becomes unusually large, in consequence of the impediment to the return of the venous blood. The ligature is to be unfastened from the notched end of the instrument, and drawn more out, so as to increase the constriction. When this is sufficient, the ligature is to be again twisted round the notch. This plan is to be followed up, till the tumour is detached, which usually happens on the fourth or fifth day.

The method now described is more simple, than those recommended by Paré, Fabricius Hildanus, Scultetus, &c. but, as Bichat and Desault advise, the knife, if possible, should always be preferred to the ligature. (*Desault par Bichat, Tom. 2.*)

I shall conclude this article with observing, that the best modern practitioners in this country prefer a common knife to any other instrument, for the performance of this operation.

TOPHUS. (said to be derived from a Hebrew word.) A swelling, which particularly affects a bone, or the periosteum. See *Note*.

TORTICO'LLIS. (from *torqueo*, to twist; and *collum*, the neck.) The wry-neck. See *Wry-neck*.

TOURNIQUET. (French, from *tourner*, to turn.) An instrument used for stopping the flow of blood into a limb, until some requisite operation has been performed, or some more permanent plans of checking hemorrhage have been put in practice.

The old surgeons used to surround the limb with a band, with which they made such a degree of constriction, that the circulation was quite stopped. These practitioners also believed, that the pressure of the band was advantageous, by benumbing the limb, and moderating the pain of operations.

The violent pain and contusion, however, which this tourniquet occasioned, being frequently followed by mortification and abscesses, surgeons endeavoured to devise some other method of checking hemorrhage. The application of the circular band was first improved, so that it caused less pain, and less mischief to the skin. The limb was surrounded with a very thick compress, over which the band was placed. Two small sticks were next put under the band; one on the inside, the other on the outside of the limb; and they were twisted till the band was rendered sufficiently tight. It is in this manner, says Dionis, in his *Traité d'Opérations*, that carriers tighten the cords which fasten the bales of goods in their carts. A

French surgeon, named Morel, is said to have made this first improvement in the application of tourniquets.

M. Petit, in 1718, presented to the Academy of Sciences a tourniquet of his own invention, which was much more perfect, than any previously contrived. It consists of two pieces of wood, one of which is superior, the other inferior. The inferior piece is about four inches and a half long, and nearly two broad. Its under surface is somewhat concave, while its upper one is a little convex, and the ends are hollowed out. From its middle part rises a round eminence, about seven lines high, and eight and a half broad. The superior piece is almost the same as the inferior one, just described, but rather shorter. The eminence, which ascends from its middle part, is six lines high, and an inch and a half in diameter. This eminence is hollow within, and calculated to receive a wooden screw, the top of which is a sort of button for turning the screw. The grooves of Petit's screw were about four, or five, and each of them four lines in diameter, in order that a half turn might produce the necessary effect. Lastly, all the pieces of the instrument were fastened together by an iron pin, which went through the middle of the two pieces of wood, and through the whole length of the screw. This iron pin was rivetted under the inferior piece, and at the top of the button, in such a manner, however, that the screw was capable of turning on it, as on a pivot.

In order to apply this tourniquet, the limb is to be surrounded with a double strap, about four finger-breadths wide, and made of chamois leather, which is the softest material which can be used. To one end of the strap a double little cushion is fastened, of the same length and breadth as the lower piece of the tourniquet. A narrow compress, or cylindrical pad, is also requisite, for the purpose of compressing the track of the vessels. This compress consists of a very firm roll of linen, covered with chamois leather. The ends of a piece of tape are sewed to the outer part of the pad, and thus the tape leaves a passage for the leather strap. By this artifice, the pad can be moved to any situation on the strap, which is most convenient, according as the bulk of the limb may require. The middle of the tape is to be fastened to the outside of the leather strap. The cylindrical compress, or pad, is to be put over the course of the vessels. The double cushion is to be placed on the opposite side of the member, while the leather strap is to surround the limb in a circular manner. All the different pieces of the apparatus are next to be retained by the tape, which is to be tied at the side of the cushion.

The tourniquet is now to be put over the

cushion, on that side of the limb which is furthest from the track of the large vessels, and is to be fastened in this situation by a double band, with a hole in it for the reception of the upper part of the screw.

In order to make the proper compression, the screw is to be half turned round, from the right to the left. The upper piece of the tourniquet becoming now further from the lower one, the double band draws the pad, and presses it against the vessels, so as to make the due degree of compression.

The following are the advantages, attending the use of Petit's tourniquet: 1. It compresses the lateral parts of the limb less, than the tourniquet previously in use. 2. It requires the aid of no assistant, either to hold, tighten, or loosen it. 3. The operator is able of himself to stop the flow of blood in the artery, by means of the screw. 4. When there is any danger of hemorrhage after an operation, this kind of tourniquet may be left on the limb, and, in case of the bleeding coming on, the patient, if no one be at hand, can tighten the instrument himself, as much as is necessary. 5. The constriction, which this tourniquet produces, does not create any danger of mortification, because it does not altogether stop the flow of blood through the collateral arteries.

The tourniquet just described is certainly very complex, when compared with that which is used by the best modern practitioners; but, still it is the original of the latter, and both are constructed on the same principles. All the pieces of modern tourniquets are kept connected together, and instead of two pieces of wood, used by Petit, there is contrived a brass bridge, which is capable of being elevated, or depressed, by means of a screw, made of the same metal. Over this bridge a very strong band proceeds, and by passing under two little rollers, at each end of the bridge, it always remains connected with the instrument. A convex firm pad is sewed to the band, and put immediately over the artery, where the instrument is applied. There are no cushions for the opposite side of the limb under the screw; but a thick piece of leather, through which the band proceeds in two places, is always situated under the lower surface of the brass, and serves to prevent any bad effects of its pressure. It is usual also for the surgeon to fold some rag, and to put it in this situation, at the time of applying the instrument. (See some other remarks on the tourniquet, in the article *Hemorrhage*.)

TRACHEA, Wounds of. See *Throat*.

TRACHEOTOMY. (from *τραχεια*, the windpipe, and *τομω*, to cut.) The operation of cutting an opening into the windpipe for various surgical purposes. See *Bronchotomy*.

TREPAN. (from *τρῦνω*, to perforate.) *Trepanum*; *Terebellum*; *Modiolus*. A circular saw, by means of which the skull is perforated in the operation called *trepanning*. It bears a considerable resemblance to the well known instrument named a wimble, and is worked in the same manner. Formerly, the saw was sometimes made of a conical shape; (see *Abaptiston*) but this construction rendered the action of the instrument difficult, and as the fear of a cylindrical saw penetrating too suddenly, so as to injure the brain, was found by experience to be an insufficient reason for the conical shape of the saw, the cylindrical trepan at length came into general use. In this country, the trepan is now superseded by the instrument, called a *trephine*, which has a different kind of handle from that of the trepan, and is not worked in the same way. On the continent, however, the trepan still has the preference.

TREPHINE. The instrument now commonly preferred for perforating the cranium, for purposes which we shall presently explain. It consists of a simple cylindrical saw, with a handle placed transversely, like that of a gimblet; and, from the centre of the circle, which the teeth of the saw describe, a sharp little perforator projects, named the centre-pin. The upper part of the centre-pin is made to screw in a corresponding hole at the inside of the top of the saw, and is capable of being taken out, or put in, at the surgeon's option, by means of a little key for the purpose. Its use is to fix the trephine, when it is first applied, that is, before the teeth of the instrument have made a sufficient circular groove, in which they can steadily work. When this has been accomplished, the centre-pin must always be removed; because now it is not only not needed, but, if left, it would retard the progress of the operation, and inevitably wound the dura mater and brain, when the teeth of the saw had cut to a certain depth through the cranium. My trephines, which I bought of M. Savigny, have their centre-pins contrived to slide up, or down, and to be fixed in either position by turning a little screw. This method seems to me both ingenious and convenient.

The cylindrical part of the trephine is often termed the *crown* of the instrument. The surgeon should have at least two, or three cylindrical saws of various sizes; for, it is always a commendable rule, never to saw away any more of the cranium, than is absolutely requisite for the accomplishment of some assignable object. There is no occasion, however, for having any more than one handle, which may be made to screw on any of the saws.

Trephines are also occasionally applied to other bones, besides those of the cra-

nium. In the articles *Antrum*, *Caries*, *Exostosis*, *Fractures of the Sternum*, *Necrosis*, *Spina Ventosa*, other cases are mentioned, in which the employment of these instruments sometimes becomes proper.

It is certainly not always desirable to remove a complete circular portion of the cranium; the taking away a piece of smaller size, and of a different shape, would frequently be much more advantageous. Some surgeons, I understand, who object to removing any unnecessary quantity of the cranium, have been in the habit of employing a trephine, terminating only in a semi-circular, instead of a circular saw, by which means, they can often cut across the base of a depressed portion of the skull, and take it away, without any occasion for removing also a circular piece of bone. An instrument of the latter kind may certainly be sometimes found useful.

The saws, however, which Mr. Hey has described, should constantly be kept in every case of trephining instruments. This practical writer remarks, that "the purposes, for which any portion of the cranium is removed, are, to enable the surgeon to extract broken fragments of bone, to elevate what is depressed, and to afford a proper issue to blood or matter that is, or may be confined, &c.

"When a broken fragment of bone is driven beneath the sound contiguous part of the cranium, it frequently happens, that the extraction cannot be executed without removing some of the unbroken part, under which the fragment is depressed. This might generally be effected with very little loss of sound bone, if a narrow portion of that, which lies over the broken fragment, could be removed. But such a portion cannot be removed by the trephine. This instrument can only saw out a circular piece. And as, in executing this, the central pin of the saw must be placed upon the uninjured bone, it is evident, that a portion of the sound bone, greater than half the area of the trephine, must be removed at every operation. When the broken and depressed fragment is large, a repeated application of the trephine is often necessary, and a great destruction of sound bone must be the consequence.

"When the injury consists merely of a fissure with depression, a small enlargement of the fissure would enable the surgeon to introduce the point of the elevator, so as to raise the depressed bone. But a small enlargement of the fissure cannot be made with the trephine. When it is necessary to apply the elevator to different parts of the depressed bone, a great deal of the sound cranium must be removed, where a very narrow aperture would have been sufficient.

"The same reasoning will apply to the case of openings, made for the purpose of

giving a discharge to extravasated blood, or matter.

"If a saw could be contrived, which might be worked with safety in a straight, or gently curvilinear direction, it would be a great acquisition to the practical surgeon. Such a saw I can now with confidence recommend, after a trial of twenty years, during which time, I have rarely used the trephine in fractures of the skull. Its use has been adopted by my colleagues at the General Infirmary in Leeds; and will be adopted, I hope, by every surgeon, who has once made trial of it." Mr. Hey next informs us, that the instrument was first shewn to him by Dr. Cockell, of Pontefract; but that there is a saw, formed on the same principle, in Scultetus's *Armamentarium Chirurgicum*. The saws alluded to are very short ones, fixed at the end of a longish straight handle; their edges are made either straight, or semi-circular. The latter construction qualifies the instrument for cutting in a curvilinear direction, which is often proper. The edge of the saw should always be made a little thicker than the rest of the blade, by which means it will work in the groove, which is cut, with more facility.

Saws, made on the principle just described, are also of infinite use in cutting away diseased portions of other bones, besides the skull, exostoses, &c. In cases of necrosis, when a dead part of a bone is quite wedged in the substance of the surrounding new bony matter, Mr. Hey's saws may often be advantageously employed for cutting away the parts, which mechanically prevent the detachment of the dead piece.

Besides trephines of various sizes, and the saws just now noticed, the surgeon should also take care to have in his case of instruments for this operation, a little brush for occasionally cleansing away the particles of bone from the teeth of the saw, in the progress of the operation; a pair of forceps adapted for extracting the round piece of bone after it has been detached by the saw; a lenticular for removing any inequalities, which may present themselves, round the sawn edge of the cranium, after the circular piece is taken out; a raspatory for the same purpose, and, also, for scraping the bone in order to see whether it will bleed, which is a circumstance in some cases very important to be attended to; (See *Head, Injuries of*;) a largish common scalpel for dividing the scalp, &c.; and some elevators for raising depressed pieces of bone.

The common elevator is now generally used by all the best English surgeons; but several others have been proposed, as, for instance, the tripod elevator; and another

one, invented by M. J. L. Petit, and afterwards improved by M. Louis.

Before beginning the description of the operation, I think it highly proper to remind the reader, of what has been so forcibly dwelt upon in the article *Head, Injuries of*,—that the removal of pressure off the brain, which pressure must also actually occasion dangerous symptoms, can form the only true and vindicable reason for employing the trephine, or sawing away any portion of the skull. There are very few exceptions to this remark: it may, indeed, be now and then proper to saw away the bony edges, which surround some fungous excrescences, which grow from the dura mater, and make their way outward, by occasioning an absorption of the part of the skull immediately over them. (See *Dura Mater*.) It may also be sometimes proper to saw out diseased portions of the skull, though, it must be confessed, that in general their separation should be left to time and nature.

In the records of surgery, innumerable facts may be consulted, where the prudent and judicious employment of the trepan has effected wonderful cures, and been the only thing by which the patients' lives could possibly have been saved. The benefit, which the operation brings about, is also sometimes so sudden and astonishing, that in no instance does the interposition of the surgical art display itself to greater advantage. The immediate restoration of sight by the depression, or extraction of an opaque substance from the eye, is not more beautiful and striking, than the instantaneous communication of the intellectual faculties, and of the powers of speech, of feeling, &c. together with voluntary motion, to a person lying in an apparently lifeless state from an injury of the head. The utility of the trepan is occasionally manifested even in this degree. In the valuable essay of Mr. Abernethy on injuries of the head, a case may be seen, in which the patient, who had been in a condition almost bereft of animation, rose up and spoke the instant the extravasated blood was removed from the surface of the brain. And amongst the wounded at the battle of Waterloo, there was a soldier of the 44th regiment, whose case is of equal interest. He had been struck with a musket ball on the right parietal bone, which was exposed, and had no appearance of being fractured. As however the symptoms of compression were urgent, and the patient was in nearly a lifeless state, I conceived it right to apply the trephine to the part on which the violence had acted. I had not sawn long before the external table came away in the hollow of the trephine, leaving the inner table behind, which was not only splintered, but driven

at one point more than half an inch into the membranes and substance of the brain. No sooner were the fragments taken out with a pair of forceps, than the man instantly sat up in his bed, looked round, and began to speak with the utmost rationality. It is a most extraordinary fact, that this patient got up and dressed himself the same day, without leave from the medical officers, and never had a bad symptom afterwards. Immediately the operation was finished, the temporal arteries were opened, and some purgative medicines exhibited.

Let not the young surgeon, however, draw from these dazzling cases of success an immoderate solicitude to perform the operation; for, it should never be undertaken but in the most pressing circumstances, and when the symptoms unequivocally shew, that a dangerous degree of pressure on the brain exists. I recollect an unfortunate example, in which the late Mr. Ramsden of St. Bartholomew's Hospital ventured to saw out a portion of the frontal bone, for a mere long continued pain in the part: the patient was attacked with inflammation of the dura mater, and perished in three or four days. We may therefore conclude, that the operation is not itself exempt from danger; and it is certain, that it ought never to be resolved on without deep consideration. "*Gravis tamen satis est operatio, ut nunquam, nisi indicationes sufficientes adsint, institui debet.*" (*Callisen Syst. Chir. Hodiern. Tom. 1, p. 658.*)

The trepan, or trephine, is never necessary in injuries of the head, except for the purpose of relieving the brain from pressure. Such pressure may be caused by a depressed portion of the cranium, or it may be produced by an extravasation of blood, or the lodgment of matter, betwixt the skull and the dura mater. The chief danger of concussion, when the accident is not directly or soon fatal from the disorganization and mischief done to the brain, depends upon the consequent inflammation of this organ, and therefore can be little likely to be benefited by the use of the trepan. If the operation becomes proper in such a case, it is when an abscess has formed under the cranium, and when the confined matter itself creates bad symptoms by its pressure on the brain. This state of things, however, cannot come on till after the inflammation of the brain and its membranes has prevailed a certain time, and it is always accompanied with a detachment of the pericranium and a puffy tumor of the scalp; or, if there be a wound of the latter part immediately over the abscess, the lips of the injury suddenly acquire an unfavourable appearance, and lose their vermilion color. The patient has also had much preceding febrile disorder, pain and tension over the whole head,

redness and turgescence of the eyes, and generally more or less delirium. When the matter is forming, there are usually some rigors, and as soon as it is formed the patient falls into a comatose state, and paralytic symptoms shew themselves. Here the urgency for the prompt application of the trephine is very great, and the patient's chance of living is almost essentially connected with the immediate performance of the operation. This important case has been particularly dwelt upon in the writings of Mr. Pott.

In the articles, *Head, Injuries of; Extravasation; &c.* we have laid down the most remarkable symptoms of concussion, and compression of the brain, a subject, which every surgeon should study with earnest attention before he ever presumes to employ the trepan. For, sometimes these accidents are extremely difficult to be discriminated; sometimes they exist together in the same individual; a complication which is peculiarly embarrassing; and, in every instance, where the symptoms are those of concussion, the operation, so far from being indicated, would be a step of all others the most likely to do harm, by increasing the irritation and inflammation of the brain and its membranes. A fall upon the back, or upon the head, occasions a direct concussion of the brain, and the shock, not being materially weakened by the intervention of any yielding elastic structure, is the more dangerous. When a person has fallen from a certain height, and pitched on his head, his back, the buttocks, the knees, or even the soles of the feet; when he has been instantly deprived of his senses, and then by degrees recovered them and come to himself again; the fact of his having suffered concussion of the brain is clear and indisputable. Concussion has likewise taken place, though in a slighter degree, when the patient has been only stunned by the fall, and experienced a sensation of sparks. But, a multitude of degrees separate this feeble concussion from that in which the substance of the brain is instantaneously disorganized, so that the patient has not the possibility of recovery.

The symptoms of concussion of the brain are attended with coma, and the compression of this organ by an extravasation is also accompanied with lethargic heaviness. How then is the surgeon to ascertain, whether the comatose disorder arises from one or the other of these affections?

Here in order to avoid repetitions, I beg leave to refer to the observations already made in the articles quoted above. But there is one criterion of such first-rate importance, that it may prevent innumerable fatal mistakes, and, indeed, without the continual recollection of it, no man ought

to be rash enough to interfere with this dark and abstruse part of surgery. On this account, I shall mention it here, notwithstanding we have already noticed it elsewhere. If the patient is knocked down and stunned directly by the blow, and remains in a state of insensibility, these primary symptoms are ascribable to the concussion. On the contrary, when the coma and loss of sense do not take place till an hour or two after the blow, they are to be imputed to an extravasation.

The shock given to the brain by concussion must, like every other impulse communicated, continue to diminish until it ceases altogether. If, at the very time of the blow, the shock has not been forcible enough to produce alarming symptoms, such symptoms will not afterwards come on when their cause is weakened. Hence, the reason may be discerned, why compression can be distinguished from concussion of the brain, when there has been an interval of sense between the receipt of the blow and the occurrence of the bad symptoms. But, the distinction of the symptoms into primary and consecutive cannot be made when concussion and extravasation exist together.

Having made these few remarks on concussion and compression of the brain, remarks, which seemed necessary before we entered into a description of the operation of the trepan, we shall next premise some observations relative to contusions and fractures of the skull, cases on which the most erroneous opinions have been entertained. It is true, that I have in another place (see *Head, Injuries of*) considered the subject; but, it may be better to recapitulate certain points here, because they have such immediate connexion with the application of the trephine.

Contusions of the head not unfrequently occasion a small kind of tumour, which is soft in the centre, but hard and resisting at the circumference, especially when the violence has been considerable. Now the ease, with which the centre or seat of the extravasated fluid admits of being depressed, while the circumference remains hard and elevated, is extremely apt to give rise to the belief, that a fracture with depression has happened. The true nature of this accident was first clearly explained by the eminent M. J. L. Petit, and since his time the proper cautions not to fall into a mistake concerning it, have been laid down by the generality of surgical writers.

Often nothing is more obscure, than the diagnosis of fractures of the cranium: their existence indeed can only be made out with certainty, when they can be felt, or seen. Thus a fracture of the skull, attended with a wound of the scalp, and exposure of the bone, shews itself in the form of a

fissure more or less wide and extensive, and taking various directions. The accident may also be known by the touch even when the soft parts continue entire, particularly if the fracture is accompanied with splinters, or the edges of the fissure are materially separated. When there are many splinters, entirely detached, a crepitus will likewise serve to explain the nature of the accident; but, unassisted by these symptoms, imparted to him by the sight, the hearing, or the touch, the practitioner cannot at once offer a decided opinion as to whether a fracture exists, or not.

In order to procure more positive information, would it be right and judicious to make several incisions and uncover the bone? But, here the surgeon would be embarrassed in the very commencement of his proceedings; for, how would he be able to judge where the knife should be applied? Why also should he resort to an useless and painful operation, which (to say the best of it) could only render the patient's cure more distant?

The symptoms, indicating compression of the brain, can alone justify an examination of the fracture. These symptoms also must be urgent and alarming; for, when they prevail in a slight degree, bleeding and evacuations promise more benefit, than any operation on the skull, and consequently all examination of the part, supposed to be broken, must be unnecessary. The precept, too commonly given, to cut through the scalp for the purpose of bringing the fracture into view, will no longer be matter of surprise, when it is known, that with some surgeons, the operation of the trepan is a thing of course in all fractures of the cranium.

Even when the cranium has been denuded, so that the sight can convey due information respecting the solution of continuity in the bone, care must be taken not to be deceived by a suture, or by the groove of a vessel. In cases of doubt, a modern surgical author advises us to scrape the outside of the bone; and he tells us, that, if after the removal of the external table, the fissure yet appear, and a thread of blood be seen at its outer part, no doubt exists of its being a real fissure. As however making this examination can answer no purpose, except with a view to determining the place where the trepan should be applied, I cannot recommend the plan, except where the symptoms are such as to render this information desirable. On the contrary, it appears to me, that all examinations of the bone, made seemingly from mere curiosity, and without any true surgical object, should be deprecated as rash and hurtful.

The danger of fractures of the skull does not depend upon the simple solution of continuity: it bears altogether a rela-

tion to the concussion and compression of the brain, with which the injury of the bone may be complicated. The pressure, which is caused by depressed splinters of bone, is less alarming inasmuch as the cause of the compression is easy of removal. The pressure arising from extravasated fluid is far more serious, in consequence of the difficulty of ascertaining positively the existence and precise situation of such extravasation.

The seat of the extravasation is sometimes between the skull and the dura mater, which has been detached from the bone. More frequently, it occurs either between the dura mater and tunica arachnoides; in the substance of the brain; or else in the ventricles. The quantity of extravasated fluid is generally less in those extravasations, which are situated between the dura mater and the skull. The extravasations, which are formed in the substance of the brain itself, are not only more considerable, but also, as they mostly depend upon concussion, are more alarming, than effusions on the surface of the dura mater. It is indeed extremely difficult, if not impossible, to ascertain the situation of the extravasated fluid. In such cases, the trepan is likewise of no use; while concussion, when so violent as to produce internal extravasation, is invariably fatal. In extravasations between the dura mater and the skull, which are almost the only cases of the kind, to which surgery can administer relief, when the effused fluid lies under a part of the skull accessible to the trepan, the extravasated fluid is almost always small in quantity. The danger, however, is not the less: ten, or twelve drops of fluid are sometimes enough to produce a fatal compression. When the extravasation has happened in the substance of the brain, the compression is far more perilous: in short, it may be said to prove with very few exceptions certainly mortal. The danger is not so great, when the extravasation is situated between the skull and dura mater.

The lethargy, the degrees of which increase from mere drowsiness into the most perfect coma; and the paralysis of the opposite side of the body to the seat of the extravasation; are the characteristic symptoms of this accident in cases of injury of the head. Having explained elsewhere (See *Head, Injuries of; Extravasation, &c.*) some other symptoms, such as stertorous respiration, dilated pupils, &c. which usually indicate pressure on the brain, it is unnecessary here to dwell upon them. The subsequent increase of the coma, and paralytic affections, and the gradual augmentation of their intensity, serve to render these symptoms distinguishable from others, which are suddenly brought on by concussion. But there are instances, as

every man of experience knows, in which concussion ruptures the blood-vessels, and produces an extravasation of blood. In this circumstance, it is obvious, that the symptoms of compression are blended with those of concussion. The symptoms proceeding from the latter cause always diminish in proportion to the time, which has elapsed from the moment of the injury; while those of compression succeed, and on the contrary, increase in intensity, in proportion as the quantity of extravasated fluid becomes more considerable. Notwithstanding these distinctions, however, it must be acknowledged, that there are many cases, in which the surgeon is obliged to remain in doubt with regard to the particular cause of the symptoms. This indecision is the more embarrassing, because the operation of the trepan is necessary in cases of extravasation, but useless in those of concussion. Even when extravasation is known to exist, the practitioner requires more information; for, he ought to know the precise situation of the effused fluid. It is true, indeed, that paralysis of one side of the body indicates the pressure to be upon the opposite hemisphere of the brain. But, what surgeon would venture to follow the practice advised by Van Swieten, and apply to the suspected side of the head three crowns of the trepan? Possibly, not one of them might fall on the situation of the extravasated fluid. When the skull is broken, the extravasation exists on the same side as the fracture. When it is the effect of concussion, or when the breach of continuity in the skull is what is termed, a counterfissure; the effusion is generally on the side of the head most remote from the blow. If the pressure is caused by a detachment of the internal table of the skull, the nature of the case cannot be ascertained before the operation of the trepan has been performed on the part of the skull, upon which the violence has acted. When there are two extravasations; one depending upon a fracture, and situated immediately under it, between the dura mater and the skull; the other arising from concussion, and situated at some point directly opposite, either between the dura mater and tunica arachnoides, or within the substance of the brain itself; paralysis may occur on the same side as the fracture, and hence, it may be inferred, that the palsy does not always take place on the side opposite to the extravasation. But, an examination of the body quickly proves, that the case does not deviate from the common rule. The extravasation, produced by concussion, being almost invariably more considerable, than that caused by a fracture, accounts for the extension of the palsy to the same side of the body. Sometimes, the side, which is not paralysed, is affected with

convulsions; the pulse is full and hard; and the respiration stertorous; in short, the symptoms are analogous to those caused by apoplexy.

The evacuating plan, recommended for the treatment of concussion, (see *Concussion and Head, Injuries of*) is all that can be done, when every thing is uncertain relative to the situation of the extravasation. It is all that can be done in those frequent instances, where the effusion has taken place in the substance of the brain, so that it cannot possibly be voided. The trepan then is indicated only when there is an extravasation between the dura mater and the bone, the fracture being situated at a part of the skull accessible to instruments, and not at the base. We will not here dwell upon the doubtful example, where the fluid lies between the dura mater and the arachnoides. But, are the cases, which we have just been describing, as frequent as they are supposed to be? Cannot the effused blood be sometimes discharged through the interspaces of the broken pieces of bone? Is the trepan usually necessary for the relief of injuries of the head, as Quesnay, Pott, and the members of the French Academy of Surgery maintained? We think not—The operation is often useless, and sometimes dangerous. I believe that it should be limited to a small number of cases, in which not only the existence and situation of the pressure are known, but in which the symptoms, arising from this cause, are urgent and dangerous, and the pressure can be removed by no other means.

Richerand contends, that extravasations between the skull and the dura mater, so considerable as to produce compression of the brain, and render the trepan necessary, are much less common, than many surgeons think. Even when they do occur, the dura mater is always detached to a certain extent, and, according to this writer, if the bone is much broken, the interspaces of the fragments are quite sufficient for the evacuation of the effused blood. The following case is quoted in proof of this observation. A woman injured her head, by falling from a height of fifteen feet. The fracture reached the whole breadth of the skull, so that when the os frontis was taken hold of with one hand, and the os occipitis with the other, the two halves of the cranium admitted of being manifestly moved and separated. Blood issued from the fissure, the edges of which were kept apart by a small wedge of wood in such a manner that the pulsations of the brain were visible. On the sixth day, as nothing was discharged from the fissure, the bit of wood was removed, and on the fifty-second the wound had completely healed without any exfoliations. On the seventy-second, the patient was discharged from the Hôtel-

Dieu perfectly cured. (*Nosographie Chirurgicale, Tom. 2, p. 292, Edit. 3.*)

Thus we see, that the trepan is often unnecessary in injuries of the head with fracture of the skull, notwithstanding the co-existence of an extravasation between the bone and the dura mater. This doctrine is very different from what is taught in the memoirs of M. Quesnay in the first volume of those of the French Academy of Surgery. Desault in the last years of his practice abandoned the operation of the trepan altogether. It has been remarked for many years, that, in the Hôtel Dieu, this operation has had very little success; a circumstance, which has excited a suspicion, that the foul air of the wards of that establishment might have had a share in bringing on the unfavourable event. We shall not here expatiate on the bad effect of the atmospheric air on the membranes of the brain; a thing, of which B. Bell seems to have convinced M. Richerand.

When the skull is fractured by a blow, or fall, and the case is a simple fissure, the trepan ought to be applied upon the solution of continuity, *if the symptoms indicate a dangerous degree of pressure on the brain*, and the edges of the fracture are not sufficiently separated to let the extravasated fluid escape.

When the detached portions of bone are depressed, so as to compress the brain, the operation is still requisite, if they cannot be elevated by other means. But Richerand maintains, that a positive indication for trepanning is not frequent, either because it is difficult to judge of the existence and situation of extravasations, or because extravasated fluids readily escape through the interspaces of the fragments, when there is a splintered fracture. Such facility is also increased, when one of the portions of broken bone is totally detached, so that it can be removed, leaving an aperture equivalent to what would be produced by the application of the trepan.

When the operation is determined on, it is more convenient to have the head shaved: indeed, this is often done immediately the surgeon is called, in order that he may have a better opportunity of seeing what parts of the scalp have been struck; for, it is in such situations, that he has most reason to apprehend fractures of the bone, or extravasations beneath it. If, however, the violence has occasioned a large wound, or laceration of the scalp, the practitioner, knowing where the force has been applied, is frequently content with having a little of the hair shaved off the parts surrounding the injury. All that need be said on this subject is, that it is always better to have enough of the hair taken away, to afford the surgeon an uninterrupted opportunity of examining the scalp freely, and doing whatever

may be necessary. The loss of a little hair is of very little consequence, while the concealment of the seat of a depressed fracture, or extravasation, might lead to fatal consequences.

When the propriety and necessity of trephining are fully indicated, provided the wound, or laceration of the scalp, should not have exposed a sufficient surface of the bone for the application of the crown of the trephine, an adequate dilatation of such wound ought immediately to be made. If, in the situation of the blow, there should only be a contusion, or a lump, unattended with any wound, a division of this part of the scalp is to be made by carrying the knife quite down to the bone. In those cases, in which the swelling, occasioned by the violence, is considerable, and attended with the sensation of a crepitus; as well as in other instances, in which there is only a contusion, under which a fracture and displaced pieces of bone may be felt; the scalp must be divided in the same manner, only with greater caution, lest the point of the knife should insinuate itself through the fracture, and do mischief to the dura mater and brain.

Authors recommend the shape of the incision to be different according to the kind of fracture, and the parts of the head, on which the violence has operated. When the whole extent of the injury can be brought into view, by means of an incision, having the form of a letter T, the surgeon should be content with such a division; but, if this be not sufficient, he may give it a crucial shape. When the trephine is to be applied to the squamous part of the temporal bone, we are recommended to make the incision, as much as possible, in the shape of the letter V, the branches of which are to be upward, and the angle downward, in order that as little as possible of the temporal muscle may be cut, and that the division of its fibres may be avoided as far as it is in our power.

Having divided the scalp, the next object is to reflect it; but, no man would be warranted in cutting any part of it away, although such practice is advised by Pott, and many other eminent writers. The purposes of the operation do not require any removal of this kind; and the method would leave a wound, which would be long in healing, and, when healed, never exempt from deformity. In short, the reflected flaps of the scalp are capable of adhering to the parts, on which they are laid, after the operation, and, consequently, ought never to be wantonly cut away.

The scalp being reflected, authors next advise us to scrape away the pericranium, either with the knife, or the raspatory.

Perhaps, this measure may be considered as one, which does neither much harm, nor much good. The design is to facilitate the application of the trephine to the bone. However, the teeth of a proper instrument, in good order, will not be impeded by the slender periosteum; and scraping this membrane away from parts of the skull, which are not to be removed, must be conducive to exfoliations.

Sometimes, the bleeding from branches of the temporal, or occipital artery, is so copious, that the bone cannot be very conveniently perforated before the hemorrhage is suppressed. If it be prudent to wait a little, and the case (as it generally does) should be likely to be benefited by the evacuation of blood, it is as well to let the bleeding continue for a certain time. The surgeon may then just direct an assistant to put the end of one of his fingers on the mouth of the vessel, and proceed in the operation. In some cases the bleeding might be so troublesome, that it would be better to tie the artery at once.

All parts of the cranium do not admit of being trephined with equal convenience and safety. It has usually been set down by surgical authors, that the trephine cannot be applied below the transverse ridge of the os occipitis. There are some cases, however, which prove that such an operation may be safely done, and that we ought not, in urgent circumstances, to be afraid of dividing the trapezius and complexus muscles, in order to be enabled to apply the trephine to the bone. (See *Hutchinson's Case in Medico-Chirurgical Transactions*, Vol. 2, p. 104, &c.)

The majority of writers also forbid us applying the trephine to the frontal sinuses, in consequence of the indeterminate depth of these cavities, and the apprehension of incurable fistulæ. M. Larrey, however, has deviated from this precept in two instances, and his practice confirms the statement of Mr. C. Bell, that by opening the frontal sinus with a large trephine and then using a small one, the internal parietes of this cavity may be trephined with perfect safety, and no risk of injuring the dura mater with the saw. (See *Larrey's Mém. de Chirurgie Militaire*, Tom. 2. p. 136—138.)

Writers also caution us not to apply the trephine to the anterior inferior angle of the parietal bone, in consequence of the middle artery of the dura mater lying under it, generally in a groove of the bone, and occasionally in a canal in its very substance. In the latter circumstance, this portion of the parietal bone could not possibly be taken away, without wounding the vessel. However, notwithstanding this advice, which has

been unthinkingly handed down by one writer to another, from generation to generation, I very much question the soundness of the doctrine. We undoubtedly ought to avoid trephining this part of the cranium, when we can prudently do so. But the causes demanding this operation are always so urgent, that the patient's sole chance of existence depends on their quick removal. Hence, were there pressure on the brain, either from a depressed portion of bone, from blood, or matter, and such pressure could not be removed without trephining the anterior inferior angle of the parietal bone, what operator would be afraid of doing so? Besides, the fear of the hemorrhage has been very unfounded; for, the lodgment of the artery in a bony furrow, or canal, which authors have pointed out, as rendering the suppression of the hemorrhage more difficult, is a mere visionary idea, as it is well known, that a little plug of lint, pushed into the orifice of a vessel, so situated, will always stop the bleeding, with as much certainty and ease as can possibly be imagined.

The foregoing suggestion was made in the early editions of my works, and I now see the safety of the practice has been confirmed. "I have also applied the trepan (says M. Larrey) over the track of the spheno-spinous artery, at the inferior anterior angle of the parietal bone. The artery was divided; but, I stopped the hemorrhage almost immediately, by applying an iron probe red hot." (*Mém. de Chirurgie Militaire*, Tom. 2, p. 138.)

Writers, until very lately, also prohibited us from trephining over any of the sutures, and, especially, over the sagittal suture, beneath which the longitudinal sinus is situated. The fear of the dura mater being injured, and of this vessel being wounded, was the reason for the advice. With regard to the sutures in general, the trephine may be applied to them, as well as to any other part; and, as for the sagittal suture, many facts confirm the propriety of not being deterred even by it, though situated immediately over the longitudinal sinus. It is to be remembered, also, that the dura mater, in cases of extravasated blood, and matter, beneath the cranium, is detached by the intervention of such fluids from the inner table.

By means of a perforation practised over the sagittal suture, Garengeot successfully elevated a portion of bone, which pressed upon the longitudinal sinus, and made the patient quite comatose. The depressed piece of the cranium could not have been so advantageously raised, had the trepan been applied in any other situation. But a

still stronger argument, in favour of this practice, when the case at all requires it, is the fact, that wounds of the longitudinal sinus, and the hemorrhage resulting from them, are not attended with any serious danger. Sharp mentions his having twice seen a bleeding of this kind. Another instance is also recorded in Warner's Cases. A child received a wound on its forehead: the two parietal bones were fractured, and a portion of each was depressed on the dura mater. The child lived a month, without any operation being done; but, at the end of this time, Warner applied the trepan. He found a splinter of bone sticking in such a way into the longitudinal sinus, that it could not easily be got out; consequently, he enlarged with a lancet the opening, in which the splinter was entangled. The hemorrhage, which was copious, was easily suppressed by the application of a little dry lint, and the child was relieved, though it died at the end of two months, after suffering a variety of symptoms, which had no connexion with the wound of the sinus, the opening of which soon healed. The fourth case, related by Marchettis, also confirms, that wounds of the longitudinal sinus are not fatal. Pott and Callisen have since recorded other facts, tending to the same conclusion. (*See Syst. Chir. Hodiernæ, Pars 1, p. 659. Edit. 1798.*)

Whenever a depressed fracture can be elevated to its proper level, without applying the trephine, and with the mere aid of a pair of forceps, or an elevator, trephining should never be performed, unless there be strong reason to apprehend, that blood, or matter, lodged on the surface of the dura mater, contributes to the occurrence of the bad symptoms, and ought to be discharged.

The scalp having been divided, if necessary, and the pericranium scraped from the surface of the bone, according to the common precepts, and practice, the next thing is the application of the crown of the trephine.

The surgeon is first to make a little impression with the point of the centre-pin, for the purpose of shewing the place, where it will work, when the crown of the trephine is applied in the proper situation; for, where such impression is made, the operator must make a small hole with a perforator, in order to fix the point of the centre-pin, on which the crown of the instrument turns backward and forward, as on an axis, during the first stage of the operation. Mr. Savigny's centre-pins make a perforation, without need of any particular instrument for the purpose, and, in this respect, are advantageous.

The point of the centre-pin having

been fixed, the trephine is to be turned, by regular semicircular motions, alternately to the right and left, which object is effected by steady pronations and supinations of the operator's hand. The teeth of the saw having made a tolerable circular groove, in which they can steadily work, the centre-pin becomes useless, and, as it would, if not withdrawn, or removed, certainly injure the dura mater and brain, by reason of its projecting further, than any other part of the instrument, it would be an unpardonable blunder to let it remain, after a proper circular groove has been formed by the teeth of the saw.

The beginning of the sawing may be executed boldly and quickly; for, the operator runs no hazard of doing mischief. It is necessary occasionally, with a view of facilitating the action of the instrument, to clean away the particles of bony matter, with a little brush, usually kept for the purpose in every box of trephining instruments. Were this plan neglected, the action of the cylindrical saw would be very much clogged.

The operator, however, must increase his caution, when the sawing has made greater progress; for, were he to be too bold, he might sometimes lacerate the membranes of the brain with the teeth of the instrument, particularly, as the thickness of the cranium is subject to infinite variety, both in different parts of the same head, and in different subjects. Let the surgeon, therefore, never forget to examine frequently with the point of a quill, whether any part of the circular groove is cut through or nearly so; for, when this is the case, the instrument must only be worked in such a way, as to make pressure upon, and cut, the part of the circle, which yet remains to be divided. In some few cases, it is said, that the surgeon can distinctly feel, when the teeth of the saw reach the diploe, or medullary structure, between the two tables of the cranium, and some writers have rashly directed us to saw with boldness, till the sensation of this occurrence is communicated to our hand and fingers. However, I believe, this possibility of discriminating the arrival of the teeth of the saw at the diploe is so uncommon, and so fallacious, that it should never be expected, or relied on. Nor ought the surgeon to saw with incautious force and rapidity, till he sees the teeth of the trephine bloody, which has been set down as another criterion of their having reached the diploe. I have already stated, that a great many skulls have hardly any space between several parts of the two tables. This is particularly often the case in old persons.

A prudent man will always prefer ex-

erting a little force for the purpose of breaking some of the bony connexion, retaining the circular piece of bone, to running any hazard of injuring the dura mater, by sawing too deeply. After a certain time, therefore, it is better to lay down the trephine, and endeavour to elevate the portion of bone, with the aid of a pair of forceps, constructed for the purpose, and kept in most cases of trephining instruments, or else by means of an elevator, which is still more calculated for the purpose.

When the circular piece of bone has been taken out, and the edges of the perforation are unequal, and splintered, the irregularities are to be cut off with the lenticular knife. When there is extravasated blood underneath the opening which has been made, it sometimes spontaneously makes its escape, and, if it should not do so, the surgeon must remove it himself. If one perforation of the skull should not suffice for letting out the blood, as much more of the cranium ought to be removed with the trephine, as circumstances may require; there being no comparison between the danger of repeating the application of the instrument, and that of leaving a quantity of undischarged, compressing fluid, on the surface of the brain. Certainly, many facts on record evince, that the dura mater may be very extensively uncovered, without dangerous consequences. Sarrau saw a whole parietal bone exfoliate, in consequence of a blow on the head. Blegny relates a similar case; and Saviard makes mention of a woman, who had lost the upper part of the os frontis, both the parietal bones, and a large portion of the os occipitis, all of which had come away at the same time. The woman, notwithstanding, recovered. Vaugion, however, who also seems to relate this identical case, describes the exfoliation as not being quite so extensive.

I am of opinion, notwithstanding these facts, that exposing a large part of the dura mater with the trephine is, by no means, an operation exempt from serious danger. And, what I conceive confirms this statement, is my having known instances, in which persons, who had been rashly advised to submit to being trephined, for the cure of violent pains in the head, &c. died, in consequence of the operation.

However, I perfectly coincide with writers, who recommend the removal of as much bone, as is requisite, in order to be able to remove the whole of the pressure from the surface of the dura mater.

The application of the trephine, in cases of large extravasations, must in

particular be made several times, when the situation of the fluid does not favour its escape. However, in this circumstance, Sabatier says, that we should not make numerous perforations all along the extent of the extravasation; but, only a counter-opening, as is done on the soft parts. This author expresses his surprise at there not being on record many examples of counter-openings made on the cranium, since analogy demonstrates their utility. I cannot help remarking on this part of the subject, that one very obvious objection to making openings of this kind in the cranium, is the impossibility of knowing with certainty, whether blood lies under any particular part of the skull; whereas, in abscesses of the soft parts, the surgeon feels the fluctuation of the matter, and knows, that his counter-opening will be made in the cavity containing it. One might also have occasion to make more than one perforation, in order to discharge blood extravasated beneath the skull, when the blow has happened near a suture, to which the dura mater continues adherent; for, it might happen, that an opening made only on one side of the suture, would only give vent to a part of the extravasation.

If we should not find blood lodged under the cranium; but the dura mater should seem elevated, tense, dark-coloured, forming a prominent fluctuating tumour, outward, it may be cautiously opened with a lancet, or bistoury, with a view of letting out any collection of blood underneath. In the article *Head, Injuries of*, we have stated the result of Mr. Abernethy's experience, in regard to the operation of opening the dura mater. This gentleman found, that the method never effectually discharged all the blood, but only the serous part of it. The evacuation of any of the compressing fluid must, however, be desirable; and, if the surgeon cannot do more, yet he has fulfilled his professional duty.

The utility of trephining is not limited to discharging extravasated blood, or matter, lodged underneath the skull. This operation frequently enables us to elevate depressed portions of bone. The latter object can often be accomplished by merely making one perforation. Sometimes, several perforations are requisite to be made near each other. Authors even state, that it may also become necessary to remove the intervening portions of bone with a pair of cutting forceps. The depressed part may then be easily raised by means of an elevator. Occasionally, indeed, I may say, very often, the best practice is to remove the depressed portion entirely, when its total separation from the rest of the skull can be accomplished by cutting across the base of the depressed piece. If any splinter stick in the dura mater, and should

not admit of being withdrawn, without enlarging the wound in the membrane, the surgeon ought not to be afraid of doing this with a sharp instrument.

According to some quick-infering writers, if, after dividing the dura mater, the surface of the brain appears smooth and flabby, with a fluctuation, we may conclude there is an abscess in its substance; and these authors, more enterprising with their pens, it is to be hoped, than with their scalpels, sanction the method of carrying the point of the bistoury to the depth of an inch, *if circumstances render so deep a puncture necessary*. "But," says Riche-
rand, "prudence forbids us to go further. Cutting the surface of the brain causes no pain, and it produces less danger, than one might apprehend; but, experience and observation have proved, that the essential parts of this organ are situated near its base, and that *its surface may be removed without danger, or pain*." (*Nosogr. Chir. T. 2, p. 301, Edit. 3.*)

After the operation of trephining, the divided scalp is to be placed as nearly as possible in its natural situation, and lightly dressed with a simple pledget of any common unirritating ointment. In applying the dressings, the surgeon should invariably keep in view these objects; namely, to let whatever is put on the wound be as light as possible, not apt to make pressure on the brain, and of a nature, which cannot excite irritation. All stimulants are to be strictly avoided; nor will any bandage be better, than an ordinary night-cap of sufficient size to be put on with facility. It may be secured with bits of tape, which are to be tied under the jaw.

The practitioner should not now conceive, that he has done all that he ought to do. Let him remember the urgent necessity of keeping off, or diminishing, the inflammation of the dura mater and brain, which is to be feared. Let him bleed the patient largely and repeatedly; exhibit saline purges, glysters, and antimonials; and if the symptoms continue, let him apply a blister to some part of the head. I shall avoid, however, any repetitions on this subject, by referring to *Head, Injuries of*.

The aperture in the skull usually becomes closed with soft granulations, which slowly acquire a hard consistence. These almost constantly grow from the edge of the perforation, and seldom from the surface of the dura mater. While the cicatrix is soft, it should be protected from external injury with a thin piece of horn, or metal. Exfoliations from the margin of the perforation sometimes retard the healing of the wound; but, now that the practice of dressing with drying spirituous applications has been exploded, and the removal of any part of the scalp is condemned by

all the best surgeons, these unpleasant consequences are rendered much less frequent, than in former days.

The reader may find an account of the operation of trepanning, or trephining, in every system of surgery; but, he should particularly consult the writings of Sharp, Le Dran, Dionis, Bertrandi, Pott, Sabatier, Abernethy, Desault, Callisen, Richerand, &c. Several parts of the *Mémoires de l'Acad. de Chirurgie* are also highly deserving of perusal.

TRICHIASIS, (derived from *Τριξ*, the hair) sometimes also named *entropion*, denotes a faulty inclination of the eyelashes inwards against the globe of the eye. According to Scarpa, the disease presents itself under two distinct forms: the first is, where the cilia are turned inwards, without the natural position and direction of the tarsus being at all changed; the second consists in a morbid inclination of the tarsus, and consequently of the eyelash towards the ball of the eye.

The first form of this disease is very rare, nor has it come under the observation of the experienced Scarpa more than once, and, in this instance, only some of the hairs had changed their direction. The second species, or form of trichiasis, or that which consists in a folding inwards of the tarsus and cilia at the same time, is that which is commonly met with in practice. It may be either complete, affecting the whole of the tarsus; or incomplete, occupying only a certain portion of the edge of the eyelid, and most frequently near the external angle of the eye. Sometimes, the disease is confined to one eyelid; at other times, it affects both; and occasionally the patient is afflicted with it in both eyes.

To these two species of trichiasis some writers have added a third, which they call *distichiasis*, and which they suppose to be produced by a double and unusual row of hairs. But, this third species, as Scarpa observes, is only imaginary, and the reason of such subdivision seems to have arisen from not recollecting, what was long ago remarked by Winslow and Albinus, that although the roots of the cilia appear to be disposed in one line only, they nevertheless form two, three, and in the upper eyelid even four rows of hairs, unequally situated, and as it were confused. Whenever, therefore, in consequence of disease, a certain number of hairs are separated from each other in a contrary direction and disorderly manner, the eyelash will appear to be composed of a new and unusual row of them, while, in fact, there has been no change, either with respect to their number, or natural implantation.

It is not an easy matter to determine precisely, says Scarpa, what are the causes, which sometimes make a few of the hairs

deviate from their natural direction, while the tarsus continues in its right position. They are commonly referred to cicatrices in consequence of previous ulceration, whereby the cilia fall off, and those which are growing are hindered from taking their proper direction. There must, however, be other causes sometimes concerned; for, in the case seen by Professor Scarpa, two or three hairs were turned inwards against the eyeball, although there had been no preceding ulceration, nor cicatrices, of any part of the tarsus. Indeed, Scarpa is inclined to believe, that the small ulcers and scars, which are sometimes formed upon the internal margin of the tarsus, are more likely to cause the second form of the disease, or the inversion of the edge of the eyelid, and, consequently, of the cilia towards the globe of the eye. As these ulcers, when neglected, destroy the internal membrane of the eyelids near the tarsus, it necessarily follows, that, in proportion as they heal and diminish, they draw along with them and turn inwards the tarsus, and hairs inserted into it. And since these little ulcerations do not always occupy the whole extent of the internal margin of the eyelid, but are sometimes confined to a few lines, in the middle, or extremity, near the external angle of the eyelid, so after the cicatrices are formed, the whole of the hairs are not invariably turned inwards, but only a certain number of them, which correspond to the extent of the ulcers previously situated along the internal edge of the tarsus. Indeed, in every case of imperfect trichiasis from a cicatrix of the inner margin of the eyelid, the tarsus and cilia are every where in their natural situation, except opposite the part, where the ulcers formerly existed. Also, if the eyelid be everted, its internal membrane, near that part of the margin corresponding to the seat of the trichiasis, will be found pale, rigid and hardened, the inversion of its cartilaginous border and of the cilia being plainly a consequence of the contraction of the cicatrized point.

Besides these causes, there are others, which may produce the complaint. Chronic ophthalmies of long continuance sometimes have this injurious effect, in consequence of the skin of the eyelids being kept for a long time in a state of distention and œdema, terminating in a relaxation of them. The cartilaginous margin of the eyelid then loses the proper support of the integuments, inclines towards the eyeball, and afterwards turns inwards, drawing the eyelashes along with it in the same improper direction. Long-continued puriform discharges from the ciliary glands likewise spoil the shape and consistence of the cartilage of the eyelid, and therefore not unfrequently occasion trichiasis. Scarpa doubts, whether a spasmodic contraction

of the orbicularis palpebrarum muscle can ever be a cause of the disease, notwithstanding what Mr. B. Bell has asserted upon the subject.

The annoyance, which must necessarily result from the hairs perpetually pressing upon the cornea and white of the eye may be easily imagined even by those, who have little acquaintance with surgery. The evil is rendered still greater by the hairs, which are turned inwards, becoming much longer and thicker, than those which retain their natural direction. And although the trichiasis be confined to one eye, both the eyes usually suffer from the effects of the disease. Indeed, generally, the eye on the sound side cannot be moved without occasioning pain in that, which is exposed to the irritation and friction of the inflected hairs. In almost all instances, both the eyes are very irritable, and incapable of bearing the light. As, in cases of incomplete trichiasis, the patient retains some little power of opening the eyelids for the purpose of seeing, and that most frequently towards the internal angle of the eye, the head and neck are often inclined in an awkward manner, so that in children a distortion of the neck and shoulders is at last produced, which cannot be rectified without difficulty, even after the trichiasis is cured. Unfortunately, also, children are impatient of the uneasiness arising from the inflected hairs, and, therefore, are continually rubbing the eyelids, which act very much increases all the ill effects of the complaint, such as the varicose chronic ophthalmia, opacity, and ulceration of the cornea.

The cure of the second species of trichiasis, or that which is commonly met with in practice, is accomplished by artificially everting the eyelid, and fixing it permanently in its natural position, together with the eyelashes, which so grievously irritate and press against the globe of the eye. According to Professor Scarpa, this indication is perfectly fulfilled by the excision of a piece of the skin close to the edge of the eyelid, of such a breadth and extent, that, when the cicatrix is formed, the tarsus and margin of the eyelid may be turned outwards, and sufficiently separated from the eyeball, the cicatrix of the integuments affording a point of support fully adequate to keeping the parts in their natural position and direction. Scarpa believes, that there are now very few modern surgeons, who, with a view to the radical cure of this disease, place any confidence, either in plucking out the inverted eyelashes; bending them outwards and retaining them so by means of adhesive plaster; or in plucking them out and destroying their roots with caustic: much less in extirpating the edge of the eyelid along with the hairs, or dividing the orbi-

cularis muscle on the internal surface of the eyelid, under an idea that the disease is sometimes produced by a spasmodic contraction of it.

The following is the mode of proceeding recommended by Scarpa: the patient being seated in a chair, if an adult, or, if a child, laid upon a table, with the head raised, and firmly held by an assistant, who must stand behind the patient: the surgeon is to push outward, with the end of a probe, the hairs, which irritate the eye. Then, with a pair of dissecting forceps, or the ends of his fore-finger and thumb, (which answer equally well, and, in many cases much better, than forceps,) the operator should lift up a fold of the skin of the affected eyelid, taking great care, that the piece, which is taken hold of, corresponds exactly to the middle of the whole extent of the trichiasis; for, as we have already explained, sometimes the whole, sometimes a half, and, in other instances, only a third of the extent of the tarsus is inverted. The surgeon, with his left hand, must raise the fold of the skin, more or less, according as the relaxation of the integuments, and the inversion of the tarsus, are more, or less, considerable. The reason of this is exceedingly evident, viz. that the greater the quantity of skin is, which is raised, the greater is the quantity which will be cut away. Supposing the patient to be an adult, as soon as the fold of skin has been raised in a certain degree, the surgeon must request him to open his eye, and, if in this act, the tarsus and eyelashes resume their natural place and direction, the portion of skin already raised will be sufficient for the purpose. We must trust to our own judgment, with regard to children, as they seldom let us have recourse to the mode of discrimination just related. When the integuments are elevated, by means of a pair of dissecting forceps, and care is taken to lay hold of the skin precisely at the middle point of the whole extent of the trichiasis, it necessarily follows, that the consequent section of the skin will form an oval, and that the greatest width of the wound will correspond exactly, or nearly so, to the middle of the eyelid, and its narrowest parts to the angles, or commissures of the same. This contributes very materially to make the cicatrix correspond to the natural fold of the eyelid, and hinder the origin of a disease of an opposite nature to the one about to be remedied, towards the angles of the eye, viz. an eversion of the commissures of the eyelids. See *Ectropium*.

Besides this caution, relative to the situation and figure of the fold of the integuments to be cut off, the surgeon must be careful, that the division of the skin be made very near the inverted tarsus.

Were this circumstance neglected, the operator might have the mortification of finding, after the wound is healed, that, although the eyelid is shortened, on the whole, from the eyebrow to the place of the recision, yet it is not equally so at the space, which is between the edge of the eyelid, and the cicatrix of the skin. Hence, the tarsus would remain inverted, as before, or not be sufficiently turned outward to keep the eyelashes from rubbing against the eye. This inconvenience would oblige the patient to submit to a second operation, done lower down, than the first.

Things being thus arranged, the surgeon, holding up the fold of skin by means of the forceps, in his left hand, is with a pair of probe-pointed, sharp curved scissors, to cut off the whole of the duplicature, being first sure, that one of the blades of the instrument is applied close to the edge of the eyelid. If both eyelids should be affected, the same operation must immediately be done upon both of them, with such cautions, and, in such proportion, as the extent of the disease, and the degree of inversion of each eyelid may require.

Scarpa next dissuades us from employing any suture to unite the wound, and represents, that it will be sufficient to keep the eyebrow as much downward as possible, if the operation has been done on the upper eyelid, or, if on the lower, to support it against the inferior arch of the orbit, by pressing it from below upwards, so as to keep the edges of the wound from becoming separated. Then the lips of the wound are to be put into exact contact, by means of strips of adhesive plaster, which should extend from the superior arch of the orbit to the zygoma, and the support of the wound in apposition will be still more securely effected by placing two compresses, one on the eyebrow, and another on the zygoma, together with a bandage.

On taking off the first dressings, the third day after the operation, the surgeon will find, that the patient can open his eye with ease, and that the inverted tarsus and eyelashes have resumed their natural position and direction. In the partial, or incomplete trichiasis, or that which only occupies a half, or a third of the whole length of the tarsus, and in subjects, who have had the skin of the eyelids very loose, Scarpa has often had the pleasure of finding the wound perfectly united on removing the first dressing.

When, however, only a part of the incision has healed, while the rest seems disposed to heal by suppuration and granulation, the surgeon is to cover the wound with small piece of lint, spread with the unguentum cerussæ; and, if the sore should become flabby, it must be touched, every

now and then, with the *argentum nitratum*, until the cure is perfected, which commonly happens in the course of a fortnight.

Thus far, Scarpa's observations have related to the radical cure of the second or most frequent, kind of trichiasis.

With regard to the first form of this disease, or that, in which the eyelashes project against the eyeball, without the natural position of the tarsus being at all altered (a case, which is fortunately very rare), the accomplishment of a cure is very difficult, since, as we have already explained, neither the pulling out of the hairs, nor burning the situation of their roots, are means at all to be depended upon for producing a complete cure of the disorder; and since, turning the tarsus, out of its natural position, would make the patient liable to an irremediable flowing of the tears over the cheek, attended with a chronic thickening of the lining of the eyelid. The treatment of this species of trichiasis is still imperfectly understood, and seems to claim more attention, than it seems hitherto to have had paid to it. In the instance of this form of the disease, which Scarpa met with, only two or three of the eyelashes inclined against the eyeball. He found, on turning the eyelid a little out, opposite to the situation of the faulty hairs, that he could not, indeed, completely put them in their natural position; but, he saw, that he could thus remove them so far from the cornea, that they would not rub against it, without altering the position of the eyelids so much as to occasion a perpetual discharge of the tears over the cheek. And, as in the patient alluded to, the skin about the eyelid was very tense, Scarpa deviated from the above rule, by making an incision with the back of the lancet, near the tarsus, three lines long, and he took away a small piece of skin of the same length; but, very little more than one line broad. When the cut healed, the operation was found to answer as well as the nature of the case would allow, though the cure was not complete, nor would the plan have obviated all inconveniences in cases of greater extent.

The trichiasis being cured, something more always remains to be done, for the purpose of correcting the cause of the disease, as well as curing the disorder of the eye, occasioned by the previous friction and irritation of the inverted hairs. The usual indications are, to restore the tone of the vessels of the conjunctiva, to lessen the swollen Meibomian glands, and to remove any cloudiness of the cornea.

Two new methods of performing the operation, for the cure of trichiasis, have been recently proposed by Dr. Crampton and Mr. Saunders.

The following is the account, which Dr.

Crampton gives of his plan, which he tried in one instance with complete success. "Let the eyelid be well turned outwards by an assistant; let the operator then with a lancet divide the broad margin of the tarsus completely through, by two perpendicular incisions, one on each side of the inverted hair, or hairs; let him then, by a transverse section of the conjunctiva of the eyelid, unite the extremities of the perpendicular incisions. The portion of cartilage, contained within the incisions, can then, if inverted, with ease be restored to its original situation, and retained there by small strips of adhesive plaster, or, perhaps, what is better, by a suspensorium palpebræ, adapted to the length of the portion of the tarsus, which it is intended to sustain, should one, or two hairs be displaced without inversion of the tarsus." (*Essay on the Entropion*, p. 55.)

Mr. Saunders entertained a favourable opinion of Dr. Crampton's operation for the cure of the disease in its early stage; but, he contended, such a vicious bending of the tarsus inward was often the consequence of repeated ophthalmia, attended with ulceration of the conjunctiva and inside of the eyelid, so that every endeavour to rectify the wrong position of the tarsus, and restore its original direction, would be fruitless. Hence, he believed, that its excision was decidedly indicated; an operation, which is said to be followed by no pain, nor uneasiness, and which is sure in its effect. No particular shortening of the eyelid ensues; the deformity is materially lessened; and, unless the cornea be already too opaque, perfect vision is re-established. Mr. Saunders directs a piece of thin horn, or a plate of silver, having a curvature corresponding to that of the eyelid, to be introduced under this part, with its concavity towards the eyeball. On this instrument, the eyelid is to be stretched. An incision is to be made through the integuments and orbicularis palpebrarum, down to the tarsus, immediately behind the roots of the cilia. The cut should extend from the punctum lachrymale to the external angle. The exterior surface of the tarsus is then to be dissected, until the orbital margin is exposed, when the conjunctiva is to be cut through directly by the side of the tarsus, which must now be disengaged at each extremity. The punctum lachrymale must be left uninjured. The operation is described as being exceedingly simple, and, if any embarrassment arises, it is from the hemorrhage of the ciliary artery, the blood sometimes obscuring the punctum lachrymale, just when the operator is about to divide the tarsus by the side of it. No dressings are required, it being merely necessary to keep the eye covered for a few days. The skin will continue to be elevated, just as the perfect eyelid was;

and though less completely, yet enough to leave the pupil clear, when the eye is moderately directed upward. In all the cases, in which Mr. Saunders operated, a fungus grew from the wound. He recommends the excrescence to be destroyed with caustic, or the knife.

Respecting this operation, I shall merely observe, that it is more severe, than that advised by Professor Scarpa, and must leave more disfigurement. Unless, therefore, the latter method prove ineffectual, I see no reason for abandoning it.

Inversion of the lower eyelid is much less common, than that of the upper one. The late Mr. Saunders never saw this disease arise from the same causes, which induce it in the upper eyelid, though he acknowledges the possibility of such a case. However, he met with several instances of the affection, in consequence of encysted tumours, which, as they increased, carried the orbital edge of the tarsus outwards, and, in the same proportion, inclined the ciliary edge towards the globe of the eye.

An inversion of the inferior palpebra is sometimes produced by inflammation and swelling of that part of the conjunctiva, which connects the eyelid with the eyeball. In cases of ophthalmia, this membrane often forms between the latter parts a distinct fold, which is situated just on the inside of the orbital edge of the tarsus, and pushes it outward; while the contraction of the orbicularis muscle turns the ciliary edge inwards, and inclines it between the swelling of the conjunctiva and the eye. In this particular case, Mr. Saunders assures us, that replacing the eyelid in the early stage of the disease, and maintaining it so, until the ophthalmia has been lessened by proper means, will be found effectual. But, when the conjunctiva is much thickened and indurated, Mr. Saunders recommends cutting such diseased part of it away, and the application of compresses to keep the orbital margin of the tarsus inward.

Albinus has recorded a species of trichiasis, which originated from the growth and inversion of one of the hairs upon the caruncula lachrymalis. The plan of relief consisted in plucking out the irritating hair; but, as Scarpa observes, it should have been mentioned, whether the hair grew again, and in what direction?

On the preceding subject, consult particularly Scarpa *sulle principali Malattie degli Occhi*; Crampton's *Essay on Entropion*; Saunders's *Obs. on several practical Points relative to the Diseases of the Eye*; Richter's *Anfangsgrunde der Wundarzneykunst*, Band. 3.

TRISMUS. (from *τριζω*, to gnash the teeth.) The locked jaw. See *Tetanus*.

TROCHAR, or TROCAR. (from the French, *trois-quart*, three-fourths, from its

point being of a triangular form.) An instrument used for discharging aqueous fluids, and now and then, matter from different cavities in the body, particularly, those of the peritoneum, and tunica vaginalis, in cases of ascites and hydrocele. Trocars are also employed for tapping the bladder, dropsical ovaries, &c.

A trocar consists of a perforator, or stilette, and of a cannula, which latter is so adapted to the first piece of the instrument, that, when the puncture is made, they both enter the wound together, with perfect ease, after which the stilette being withdrawn, the cannula remains in the wound, and gives a ready passage for the fluid outward.

Such are, the use of a trocar, and the principle, on which it should be constructed. It would be unnecessary in this work to detail every little particularity in the instrument. I shall just observe, that the triangular-pointed trocars seem to retain the greatest share of approbation; for, although those of a flat, lancet-pointed shape enter parts with more ease, their cannulae are not large enough for the ready escape of fluids, which are at all thick, gelatinous, or blended with hydatids, and flaky substances.

The trocar, which is used for puncturing the bladder from the rectum, should be eight, or nine inches long, and of a curved form.

Surgeons ought always to have at least three trocars; one of full size; another of middling width; and a third of small dimensions. In cases of hydrocele, the latter is often preferable to a larger one.

TRUSS. (*trousse*, French.) *Bracharium*. A bandage, or apparatus, for keeping a hernia reduced.

Trusses are either of an elastic or non-elastic kind: the latter cannot be much depended upon, and are now seldom employed. The *spring* is a very essential part of every elastic truss, and it consists of a narrow piece of steel, which is adapted to the side of the body, on which the hernia is situated. The front part of the steel spring has an expanded form, and, when the truss is properly applied, ought to be situated over the mouth of the hernial sac. Under the back surface of the anterior end of the spring is placed the pad, which should be adapted in shape and size to the passage, which it is intended to shut up. The steel spring is usually covered with leather, is lined with soft materials, and after being put on the patient, it is fastened in its situation by means of a strap, which extends from the two ends of the spring, round that side of the body, on which the hernia is not situated.

When the pad of the truss cannot be kept from rising too high, another strap,

passing under the thigh from the back of the spring to its anterior end, becomes necessary. Sometimes, a band, extending over the shoulder, is requisite for keeping the pad from descending too low.

The springs of trusses, intended for children, and persons, who do not undergo much labour and exertion, need not be made so strong, as those designed for hard-working, active people.

The idea, that children cannot wear steel trusses, is as erroneous, as it is dangerous in its practical consequences. Mr. Pott has strongly written against this ill-founded supposition.

When great pressure, and a very strong spring, are found necessary for keeping a hernia securely reduced, and the spermatic cord swells and inflames in consequence of such pressure, it is better to have a little excavation in the pad, for the reception of this part.

Some trusses are formed with pads, which are moveable on a rack, so that their position can be altered, and adapted to the parts, with the greatest ease.

A compress of calico, placed under the pad, preserves the instrument from the effect of perspiration, and makes the truss fulfil its object in a better manner.

In the article *Hernia*, we have given an account of the truss for umbilical hernia, invented by Mr. Morrison, and described by Mr. Hey. In the same part of this Dictionary may also be found some observations, relative to the place, against which the pressure of the pads of trusses should be directed in cases of inguinal hernia, in conformity to Mr. A. Cooper's description of the situation, at which the parts first protrude from the abdomen.

TUMOUR. A swelling. In the present article, I merely intend to treat of, what are usually called, sarcomatous and encysted tumours. Mr. Abernethy thinks, that the manner in which tumours are formed is best illustrated by those, which hang pendulous from the membranous lining of different cavities. This gentleman adverts to an example noticed by Mr. Hunter, in which, on the cavity of the abdomen being opened, there appeared lying upon the peritoneum, a small portion of red blood recently coagulated. This, on examination, was found to be connected with the surface, upon which it had been deposited, by means of an attachment, half an inch long, and this neck had been formed before the coagulum had lost its red colour, (See *Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge*, Vol. 1, p. 231.) Mr. Abernethy observes, that if vessels had shot through the slender neck, and organized the clot of blood, this would then have become a living part: it might have grown to an indefinite magnitude, and its nature and

progress would probably have depended on the organization, which it had assumed. He mentions his having in his own possession a pendulous fatty tumour, which was found growing from the surface of the peritoneum, and which was undoubtedly formed in the same manner as the tumour noticed by Mr. Hunter, viz. by vessels shooting into a piece of extravasated blood, or lymph, and rendering it a living organized substance. Tumours, in every situation, and of every description, are probably formed in the same way. The coagulating lymph being effused, either accidentally, or in consequence of disease, is afterwards converted into a living part, by the growth of the adjacent vessels and nerves into it. Mr. Abernethy remarks, that, when the deposited substance has its attachment by a single thread, all its vascular supply must proceed through that part; but, in other cases, the vessels shoot into it irregularly at various parts of its surface. Thus an unorganized concrete becomes a living tumour, which has at first no perceptible peculiarity as to its nature. Although its supply of blood is furnished by the vessels of the surrounding parts, it seems to live and grow by its own independent powers, while its future structure seems to depend on the operation of its own vessels. Mr. Abernethy conceives, that the altered structure of an enlarged gland affords no contradiction to the above account, as, in this latter case, the substance of the gland is the matrix, in which the matter forming the tumour, or enlargement, is deposited. According to Mr. Abernethy, the structure of a tumour is, sometimes, like that of the parts, near which it grows. Such, as are pendulous in joints, are cartilaginous, or osseous. Fatty tumours, he observes, frequently form in the midst of the adipose substance, and he has seen some tumours growing from the palate, which had a slender attachment, and resembled the palate in structure.

However, this resemblance of the structure of a tumour, to that of the neighbouring parts, is not always observable. I have in my own possession a completely cartilaginous tumour, which I found in the midst of the fat near the kidneys. The pendulous portion of fat, growing from the peritoneum, and mentioned by Mr. Abernethy, serves as another instance of the fact; and, one might add, that every polypus, which we meet with, bears no resemblance in structure to the neighbouring parts. Mr. Abernethy mentions his having seen bony tumours, which were unconnected with bone, or the periosteum, and he observes, that the structure of a tumour is, in general, unlike that of the part, in which it is produced.

When the coagulable part of the blood is effused, and the absorbents do not take it away, the surrounding blood-vessels grow into it, and convert it into a vascular tumour. The effusion of the coagulable part of the blood may be the effect of accident, or of a common inflammatory process, or it may be the consequence of some diseased action of the surrounding vessels, which (diseased action) may influence the organization, and growth of the tumour.

In the former cases, the parts surrounding the tumour may be considered simply as the sources, from which it derives its nutriment, whilst it grows apparently by its own inherent powers, and its organization depends upon actions begun and existing in itself. If such a tumour be removed, the surrounding parts being sound, soon heal, and a complete cure ensues. But, if a tumour be removed, whose existence depends on the disease of the surrounding parts, which are still left, and this disease be not altered by the stimulus of the operation, no benefit is obtained. These parts again produce a diseased substance, which has generally the appearance of fungus, and, in consequence of being irritated by the injury of the operation, the disease is in general increased, by the means, which were designed for its cure. It appears, therefore, that in some cases of tumours, the newly formed part alone requires removal, whilst, in others, the surrounding substance must be taken away, or a radical cure cannot be effected. (*Surgical Observations, by John Abernethy, F. R. S. &c. 1804.*) This gentleman conceives, that the irritation of the tumour itself, when once the swelling has been produced, keeps up an increased action in the surrounding vessels, so as to become a sufficient cause of the disease continuing to grow larger. As the tumour becomes of greater magnitude, it condenses the surrounding cellular substance, and thus makes for itself a sort of capsule. The close, or loose manner in which tumours become connected with the surrounding parts, seems to depend very much on the degree of irritation, and inflammation excited in the circumjacent parts. When a tumour has been at all tender, painful, and inflamed, it is generally found intimately adherent to all the neighbouring parts. Mr. Abernethy conceives, that the increased irritation, which a tumour creates, when it has exceeded a certain size, may explain, why some tumours, which are at first slow in their progress, afterwards begin to grow with great rapidity.

The process, by which tumours are formed, is commonly thought to be attended with an increased action of the vessels, which supply the swellings with

blood. It is supposed, in short, to be the same kind of process, which forms all the thickenings and indurations, which, under various circumstances, occur in all the different parts of the human body. It has sometimes been named *chronic inflammation*, to distinguish it from that, which is more quick in the production of certain effects, and is attended with a manifest throbbing in the part affected.

It seems generally to be admitted, that the growth of all tumours may always be retarded, and that sometimes, they may even be diminished by means of topical bleeding with leeches, and keeping the parts in a continually cool state, by the incessant application of cold sedative washes. Afterwards, when the increased action of the vessels seems checked, and the tumour ceases to enlarge, discutients are indicated, such as frictions with mercurial ointment, pressure, electricity, rubefacient plasters, solutions of salts, blisters, and issues. Very few sarcomatous or encysted tumours, however, are ever completely removed by these local means. The swelling, on the contrary, generally increases, notwithstanding them, and the irritation of these diseases by the latter stimulants, is not altogether unattended with danger of the affections becoming changed by them into very malignant, and dangerous cases, sometimes to all appearances, cancerous. The most advisable plan is to recommend the removal of all these tumours with the knife, while they are small, and in an incipient state. For thus they are got rid of by an operation, which is certainly trivial, compared with the one, which may afterwards become requisite, when the disease has attained an enormous magnitude.

TUMOURS, SARCOMATOUS. These have been so named, from their firm, fleshy feel. They are of many kinds, some of which are simple, while others are complicated with a malignant tendency. Mr. Abernethy has attempted to form a classification of sarcomatous tumours, for the different species of which he has proposed names, deduced from the structure, which they exhibit on dissection. This gentleman has named the kind of swellings, which he first considers, *Common Vascular*, or *Organized Sarcoma*. Under this title, Mr. Abernethy includes all those tumours, which appear to be composed of the gelatinous part of the blood, rendered more or less vascular by the growth of vessels through it. The vessels which pervade this substance are, in different instances, either larger, or smaller; and more, or less numerous; being distributed in their usual arborescent manner, without any describable peculiarity of arrange-

ment. Perhaps, all the varieties of sarcomatous tumours are at first of this nature. The structure, under consideration, is met with not only in distinct tumours, but, also, in the testis, mamma, and absorbent glands. When a common vascular, or organized sarcoma, has attained a certain magnitude, the veins of the skin seem remarkably large, and their winding under the integuments excites notice. This kind of sarcoma is not at all tender, so that it may be freely handled, and also electrified, without giving pain. The tumour sometimes grows to such a size, that the skin bursts, the substance of the swelling sloughs out, and the disease is got rid of. However, this mode of cure is attended with such terrible local appearances, and so much fever, &c. that the removal of the disease with the knife is to be preferred.

The second kind of sarcomatous tumour, noticed in Mr. Abernethy's classification, is the *Adipose Sarcoma*. Every one, at all in the habit of seeing surgical diseases, must know, that fatty tumours are exceedingly common. There can be little doubt, that these swellings are formed in the same manner, as others, viz. in the first instance, they were coagulable lymph, rendered vascular by the growth of vessels into it, and that their future structure depended on the particular power and action of the vessels. Adipose sarcomatous tumours always have a thin capsule, formed by the simple condensation of the surrounding cellular substance. It adheres very slightly to the swellings, and, chiefly by means of vessels, which pass through this membranous covering in order to enter the tumour. As Mr. Abernethy has accurately described, the vessels are so small, and the connexion so slight, that, in removing the tumour, no dissection is requisite, as the operator may easily put his fingers between the swelling and its capsule, so as to break the little vascular connexions, and entirely detach the disease.

Adipose tumours are never furnished with any large blood-vessels, and the fear of hemorrhage, which frequently deters surgeons from operating, is very unfounded. It is an undoubted fact, that there is no species of tumour, that can be removed with so much celerity, with such apparent dexterity, or with such complete security against future consequences, as those of an adipose nature. However, now and then, when the tumour has been at all in an inflammatory state, the capsule becomes thickened, and intimately adherent to the surface of the swelling, so that the separation of the disease is more difficult, and requires the knife to be longer employed. The tumour also sometimes

becomes, after inflammation, closely adherent to the contiguous parts. Adipose tumours often acquire an enormous magnitude; Mr. Abernethy relates an example of one, removed by Mr. Cline, which weighed between fourteen and fifteen pounds. In this state, of course, the immense size of a wound, requisite for the removal of the tumour, must be dangerous, and it is a strong argument in favour of having recourse to the operation at an earlier period.

The next species of sarcoma, noticed in Mr. Abernethy's classification, is what this gentleman names *pancreatic*, from the resemblance of its structure to that of the pancreas. This kind of disease, according to Mr. Abernethy, is occasionally formed in the cellular substance; but, more frequently, in the female breast, on that side of the nipple, which is next to the arm. When a pancreatic sarcoma is indolent, and increases slowly, the surrounding parts, and the glands in the axilla, are not affected. But, some of these swellings deviate from their common character, and become of a very irritable nature, occasioning severe and lancinating pain, and producing an inflammatory state of the skin covering them, so that it becomes adherent to their surface. The absorbents leading to the axilla are also irritated, and the glands enlarged. Pancreatic sarcomas do not grow to a very large size; but, when their progress is unrestrained, the pain, attendant on the disease, becomes lancinating, and so severe, as to make the patients feverish, and lose their health and strength. Mr. Abernethy remarks, that, when the axillary glands become affected, one generally swells at first, and is extremely tender and painful; but, afterwards the pain abates, and the part remains indurated. Another then becomes affected, and runs through the same course.

Another species of sarcoma, Mr. Abernethy has characterized by the epithet *mastoid* or *mammary*, from the resemblance which this gentleman conceives its structure bears to that of the mammary gland. This kind of disease, Mr. Abernethy says he has not often seen. In the example, which he met with, the tumour was about as large as an orange, and situated on a woman's thigh. The swelling was removed by an operation; but, the wound afterwards degenerated into a malignant ulcer, attended with considerable induration of the surrounding parts, and the woman died of the disease in two months. Mr. Abernethy conceives, that the whole of the morbid part had been cut away, but, that the contiguous parts had a disposition to disease, which was irritated by the operation, and, that if the

nature of the case could have been known beforehand, it would have been right to have made a freer removal of the substance surrounding the tumour.

Mr. Abernethy places the mastoid sarcoma, between such sarcomatous swellings as are attended with no malignity, and the following ones, which have this quality in a very destructive degree.

The *tuberculated* sarcoma is composed of a great many small, firm, roundish tumours of different sizes and colours, connected together by cellular substance. Some of the tubercles are as large as a pea; others equal a horsebean in size; most of them are of a brownish red colour; but some are yellowish. Mr. Abernethy mentions his having seen this species of sarcoma chiefly in the lymphatic glands of the neck. The disease proceeds to ulceration; becomes a painful and incurable sore; and ultimately occasions death.

Another kind of sarcoma, mentioned in Mr. Abernethy's classification of tumours, is distinguished by the epithet *medullary*, from its having the appearance of the medullary matter of the brain. It appears to be an exceedingly malignant disease; communicates to the lymphatic glands a similar distemper; ulcerates and sloughs, and at last proves fatal. It is particularly apt to make its attack on the testis, and it is treated of in another part of this book. (See *Testicle, Diseases of*.)

Mr. Abernethy includes also in his classification *carcinomatous* sarcoma. (See *Cancer*.)

I must refer to another article, (*Mamma, Removal of*) for an account of the plan of operating in removing sarcomatous tumours.

One of the boldest operations of this kind, ever undertaken, was that lately performed by Mr. Goodlad, of Bury, in Lancashire. The case was an immense tumour, situated on the left side of the face and neck, and the base of which was about twenty-eight inches in circumference. The disease extended from the external canthus of the eye above to within three quarters of an inch of the clavicle below, and some idea of the depth of its attachments may be conceived, when it is known, that the whole parotid gland was involved in it. For the purpose of obviating all danger of hemorrhage, Mr. Goodlad began with tying the carotid artery. The nature of the operation will be best understood by adverting to the appearances afterwards presented by the wound. "The whole sterno-mastoid muscle was exposed, and its fibres dissected clean, except about half an inch from its insertion into the clavicle. The wound extended backwards

from behind the mastoid process to the trachea anteriorly, but became narrower in the direction of the muscle at the lower part of the neck. The submaxillary gland was exposed, and about one fifth of its substance, not appearing healthy, was removed. The digastric and the greater portion of the mylo-hyoideus were exposed. The ramus of the jaw was only covered by periosteum, except where covered by the masseter muscle, part of which, not appearing healthy, was dissected away. The whole of the condyloid process of that bone was laid bare in the same manner, and behind it the pterygoid muscles were also exposed. The membrane of the cheek was only covered by a cellular substance, which did not appear healthy; but, sufficient skin was saved to cover the zygoma. *The parotid gland was entirely removed.*" This enormous wound healed in ten weeks. (See *Medico-Chirurgical Transactions*, Vol. 7, p. 112, &c.)

Respecting the foregoing severe operation, many surgeons may be inclined to doubt the propriety of tying the carotid artery, as a preparatory step, and, indeed, it is positively condemned in an anonymous note attached to the above case, simple temporary pressure on the exposed vessel being represented as preferable. It appears to me, however, that Mr. Goodlad's method was justifiable, and on the whole the best, because the application of the ligature to the carotid not only removed the dangers of hemorrhage during the operation, but obviated them afterwards, and no doubt lessened the necessity for a prodigious number of ligatures for vessels, which would otherwise have poured out a profuse quantity of blood.

On the question, whether it would not have been better to have been content with simply tying the carotid artery, and tried, whether stopping this large supply of blood to the diseased parts, would not have been followed by an absorption of the tumour, probably all surgeons will not entertain an unanimous opinion. The success of Mr. Goodlad's operation, and the uncertain efficacy of the other plan, will no doubt incline many practitioners to prefer the bold method of extirpation. Yet, others will perceive, that such an operation, notwithstanding its success in the example before us, was dreadfully severe, and would of itself in the generality of cases have fatal consequences. They will also be encouraged, in any similar instance to try the effect of the ligature, by the cure which Mr. A. Cooper has lately accomplished, of an enormous cutaneous enlargement of the lower extremity by tying the artery in the groin. Indeed, I am sure, that as the improvements in modern surgery advance, the plan of curing tumours by cutting off their main supply of blood, will be much

more extensively adopted, than has hitherto been the case. In this way, the surgeon may attempt the dispersion of many tumours, which could not be meddled with in any other manner, and which, if left to themselves, must have a fatal termination.

TUMOURS ENCYSTED. These, which are also commonly named wens, consist of a cyst, which is filled with different substances. When the contained matter is fatty, it is termed a *steatoma*; when somewhat like honey, *meliceris*; when like pap, *atheroma*. These are the three species, into which writers usually divide encysted tumours. However, some of these swellings do not conform to either of the above distinctions, as their contents are subject to very great variety indeed, and are occasionally of an earthy, bony, or horny nature. It is said, that some encysted tumours of the latter description have occasionally burst, and assumed the appearance of horns, by the gradual projection of the matter secreted in their cysts. (See *Home's Obs. on this Subject, in the Phil. Trans.*) I remember seeing an excrescence of the kind alluded to, removed some years ago from the scrotum of a man in St. Bartholomew's Hospital. Sir James Earle performed the operation, and, if I am not mistaken, the preparation of the disease is in Mr. Abernethy's museum.

I suppose every body in London has now seen in the British Museum the horn deposited there as a curiosity, and which, with another of the same size, grew upon the head of a human subject. What is equally curious, hairs are not unfrequently found growing in the cavities of encysted tumours, (*Delpech Précis des Maladies Reputées Chirurgicales*, Tom. 3, p. 412.); and even teeth, more or less perfectly formed, have been strangely met with in the same situations. An interesting specimen of the latter occurrence, in a double encysted tumour in the orbit, has been recently published by my friend Mr. Barnes, of Exeter. (See *Medico-Chir. Trans.* Vol. 4, p. 316.)

Encysted tumours are generally of a roundish shape, and are more elastic, than fleshy swellings. However, the latter circumstance depends very much on the consistence of the contents, and the thickness of the cyst. As far as my observation extends, encysted tumours form more frequently on the head, than any other part; but, they are very frequently met with in all situations under the integuments, and sometimes in deeper places. Encysted tumours are also very often seen on the eyelids.

Some surgeons have tried to cure encysted tumours by pricking them with needles, and squeezing out their contents; or by applying stimulating, and discutient

applications to them. This practice, however, is by no means prudent; for, it seldom succeeds, and sometimes, in consequence of making the cyst ulcerate, it induces a terrible disease, in which a frightful fungus shoots out from the inside of the cyst, attended with immense pain and irritation, and often proving fatal. In order to confirm this statement, I shall quote the following case, recorded by Mr. Abernethy.

A gentleman, of a stout make, and about forty years of age, had a tumour, supposed to be sarcomatous, which had formed beneath the integuments on the lower edge of the pectoral muscle. It was occasionally attended with severe pain, in which state it rapidly increased in size, and produced a great deal of fever and irritation, which made him look very sickly, and emaciated. Some persons even considered the disease cancerous.

When the tumour had acquired a magnitude of about four inches in length, and three in breadth and depth, he submitted to its removal; the integuments were divided and turned back, and the tumour dissected off the surface, and, in some degree, from under the edge of the pectoral muscle.

When the tumour was examined, it was found to be composed of a steatomatous substance, contained in a thin capsule. The substance resembled that, which I have described as being sometimes found in cells in the testis, or intermixed with the diseased organization of that part. It was firm, and resembled cheese in its yellow colour and unctuous appearance; but, it was not unctuous to the touch.

The wound made in the operation soon healed, and the patient's health was restored to as good, or seemingly a better state, than before the formation of this disease. He also regained his usual athletic form. But, in less than three months after his recovery, two new tumours formed, one above, and the other below the cicatrix of the wound. The patient did

not particularly attend to them till they had attained a size equal to that of a large walnut. To dissect out both these tumours, and make so free a removal of parts as to render it probable, that no new growth would ensue, seemed to be a very formidable operation; and, as the nature of the former tumour was known, and it was supposed, that these were of the same nature, it was agreed to puncture the upper one, to express the contents, and await the event. This was done by a puncture of half an inch in length, made by an abscess lancet. The contents were exactly like those of the original tumour. Vehement erysipelatous or irritative inflammation took place, and sloughing about the diseased part: the inflammation rapidly extended to the opposite side of the thorax, and then down the integuments of the abdomen to the groin. The derangement of the constitution was as violent as the local disease, and, in about a week, the patient died. (*Surgical Observations*, 1804, p. 94.)

Similar, alarming, fungous diseases are also apt to arise, whenever the surgeon, in cutting out encysted tumours, leaves any part of the cyst behind.

The most advisable method is to have recourse to the knife, before an encysted tumour has attained any considerable size. When it is large, however, before the operation is resorted to, a portion of the skin must be taken away with the swelling in the manner mentioned in the article *Mamma, removal of*. The chief piece of dexterity in the operation consists in detaching all the outside of the cyst from its surrounding connexions, without wounding it. Thus, the operator takes the part out in an entire state, and is sure, that none of the cyst remains behind. When the cyst is unskilfully opened, some of the contents escape, it collapses, and the dissection is rendered more tedious and difficult.

TYMPANUM. For an account of its diseases, see *Ear*.

U.

ULCERATION, is the process, by which sores, or ulcers, are produced in animal bodies. In this operation, the lymphatics appear to be, at least, as active as the blood-vessels. An ulcer is a chasm formed on the surface of the body by the removal of parts back into the system by the action of the absorbents. At first, it may be difficult to conceive how a part of

the body can be removed by itself; but there is not more difficulty in conceiving this, than how the body can form itself. Both facts are equally well confirmed. When it becomes necessary, that some whole living part should be removed, it is evident, says Mr. Hunter, that nature, in order to effect this object, must not only confer a new activity on the absorbents;

but, must throw the part to be absorbed into a state, which yields to this operation. The absorption of whole parts in disease, arises from five causes; pressure; irritation of stimulating substances; weakness; inutility of parts; death of them. (*Hunter on Inflammation, &c. p. 442—446.*)

Ulceration, or, in other terms, absorption, takes place much more readily in the cellular, and adipose substance, than in muscles, tendons, ligaments, nerves, and blood-vessels. Hence, in the progress of pus to the surface of the body, ulceration often takes a circuitous course for the purpose of bringing the matter to the skin. The skin itself, also, being highly organized, considerably retards the bursting of abscesses. It is on this same account, that, when ulceration is spreading, the edges of the skin hang over the ulcerated surface. (*Hunter, p. 447.*)

New-formed parts, such as cicatrices, callus, and all adventitious new matter, such as tumours, readily admit of being absorbed. The adventitious matter, indeed, is more prone to be absorbed, than that which is a substitute for the old. Mr. Hunter explained this circumstance on the principle of weakness.

When ulceration takes place, in consequence of the death of an external part, it occurs first on the outer edge, between the dead and living substance.

Abscesses constantly make their way to the surface of the body by ulceration; but, as some textures more readily admit of being absorbed, than others, the matter often follows a circuitous course, before it can arrive at the skin. (*Hunter, p. 448, 449.*)

A tumour, when it makes equal pressure in every direction around, will only make its way in an external course, because what Mr. Hunter termed interstitial absorption happens in no other direction. (*P. 449.*)

The parts, which are situated between an abscess, or any extraneous substance, and the nearest surface, are those, which are most susceptible of ulceration. This is one of the most curious phenomena, connected with the process under consideration. It shews, that there is a principle in the human body, by which parts are always prone to free themselves of disease. Slight pressure from without will often produce a thickening of parts, and hence, Mr. Hunter remarks, there even appears to be a corresponding backwardness to admit disease. (*P. 449.*) Both these facts, he observes, are shewn in the case of fistula lachrymalis; for, though the matter is nearest the cavity of the nose, still it makes its way externally, by means of ulceration, while the Schneiderian membrane even becomes thickened, so as to become a bar-

rier against the progress of the disease inward. (*P. 451.*)

There is one difference, between the advancement of an encysted tumour to the surface of the body, and the progress of an abscess in the same direction, viz. that the former does not excite ulceration of the cyst; but, an interstitial absorption of the sound parts, between the cyst and skin, till the cyst and external skin come into contact, at which period, inflammation takes place, and absorption becomes accelerated into ulceration. In an abscess, the progressive ulceration begins in the cyst, at the same time, that the interstitial absorption in the sound part, covering the matter, is going on. (*P. 452—457.*)

The action of progressive absorption is to remove surfaces contiguous to irritating causes, which Mr. Hunter referred to pressure, irritation, and weakness. In cases of tumours, pressure becomes a cause. The buttocks and hips of persons, who lie long on their backs, often ulcerate. The heels of many patients, with fractures, who lie for a great while in the same position, are apt to ulcerate. In the latter instances, Mr. Hunter conceived, that ulceration is a substitute for mortification, and is, at the same time, a proof of a certain degree of strength; for, if the patient's constitution were very weak, the same parts would mortify. (*P. 453.*) That pressure is a frequent cause of ulceration, is also evinced by the occasional effects of chains on prisoners, and harness on horses.

That irritating substances produce ulceration, needs no illustration.

Progressive absorption may occur either with, or without suppuration. We have instances of the latter in cases of extraneous bodies, which travel about the body, without producing irritation enough to give rise to the secretion of pus. In the progress of aneurisms of the aorta, and of fungous tumours of the dura mater to the surface, the same fact is also illustrated. (*P. 455.*)

Absorption with suppuration, in other words, ulceration, either happens in consequence of suppuration already begun, in which event the pus acts as pressure; or else absorption attacks external surfaces from particular irritations, or weakness, in which case, suppuration must follow. (*P. 456.*)

The production of ulceration requires much greater pressure from without, than from within. The process is always disposed to take place more quickly, when near the surface of the body, and its progress becomes accelerated, in proportion as it arrives near the skin.

The adhesive inflammation precedes the

suppurative, and prevents the pus from becoming diffused, as soon as it is secreted, and when the cyst afterwards ulcerates, in order to let the matter approach the skin, the adhesive inflammation still continues to go before the ulcerative process, and thus prevents the matter from insinuating itself into the interstices of the cellular substance. (P. 457.)

The pain of ulceration is, in some degree, proportioned to its quickness. When ulceration begins on a surface, or takes place for the purpose of bringing matter to the skin, the pain is always considerable. When ulceration takes place, in order to separate a dead part, as in sloughing, exfoliations, &c. there is seldom any particular pain. (P. 459.)

The ulcerating sore always exhibits little cavities, while the edge of the skin is scalloped, and thin, at the same time, turning a little out, and overhanging, more, or less, the ulcerated surface. The face of the sore appears foul, and the discharge is very thin.

When ulceration stops, the edges of the skin become regular, smooth, a little rounded or turned in, and of a purple colour, covered with a semi-transparent white. (Hun'er on Inflammation, &c. p. 460.)

The reader, desirous of further information, should particularly consult this last publication, and Professor Thomson's *Lectures on Inflammation*, p. 349, &c.

ULCERS. Surgeons usually define an ulcer to be a solution of continuity in any of the soft parts of the body, attended with a secretion of pus, or some kind of discharge.

In the present part of this Dictionary, there will not be occasion to speak of several kinds of sores, which have been treated of in other articles. (See *Cancer*, *Scrophula*, and *Venereal Disease*.)

Ulcers are divided into *local* and *constitutional*. As Professor Thomson has well observed, however, it is only within certain limits, that this distinction is well founded; for, an ulcer, which is at first completely local, may in time affect the system, so as to become constitutional; and ulcers, which derive their origin from some general affection of the system, may remain after the removal of the constitutional disorder, by which they were originally produced. (*Lectures on Inflammation*, p. 427.)

"Ulcers (says Dr. Thomson) have usually been distinguished from each other by the causes by which they are induced, by the symptoms which they exhibit, and by the parts of the body in which they occur. The want of a disposition to heal in a suppurating surface may depend upon some specific action in the cause, from which it proceeds, upon something peculiar

in the constitution of the patient in whom it exists, or merely upon an improper mode of management: and, hence, the distinction, that has long been made, of ill-conditioned sores, or ulcers, into those which are *specific* in their nature, and into those which are *simple*.

"Specific sores, or ulcers, may be occasioned by specific poisons, or by particular diatheses. The sores, or ulcers, which arise from specific poisons, may be either *local*, that is, confined, like a primary syphilitic ulcer, to one spot; or *constitutional*, that is, liable to occur in any part, texture, or organ, such as secondary syphilitic ulcers. Of diatheses, predisposing to ulcers, we have examples in the scrophulous, scorbutic, and arthritic diatheses, and also in the syphiloid diathesis, or that which arises not unfrequently in those, who have had syphilis, from the too free and injudicious use of mercury.

"Every ulcer, strictly speaking, is of a local nature; but, there are ulcers, which, though necessarily local in their appearance, are connected with, or dependent upon, diseases, which affect the general system. These ulcers ought to be regarded as modifications of, or forms in which the diseases appear, with which they are connected. Considered in this light, it is obvious, that specific ulcers can be treated of with propriety, only under the head of the diseases, to which they respectively belong.

"We call those sores, or ulcers, *simple*, which do not appear to proceed from any specific disease, or morbid diathesis existing in the constitution of those, in whom they take place. They are usually solitary occurrences, and the consequences of accidental injuries, and improper modes of management. They may occur in every part of the body; but, they appear most frequently upon the lower extremities."

Professor Thomson afterwards remarks, that "the appearances, which different ulcers exhibit, seem, at first view, to afford an excellent foundation for distinctions among them, and so they undoubtedly do in many respects."

But, (says he) "it is to be regretted, that the characters, upon which the distinctions of ulcers, as well as of many other local diseases, are founded, are neither very uniform in their appearance, nor very easily distinguishable from one another. Not only are the local appearances, which present themselves, in simple ulcers, liable to great variations in the different stages of the same individual affection, but, they are often apparently the same with, or at least not easily distinguishable from, those which occur in specific diseases, and which require, for their cure, peculiar modes of treatment. It is this

circumstance, which renders it so necessary for us, in endeavouring to distinguish and to cure ulcers, to avail ourselves of all the information, which we can procure from the history of the ulcer, from the nature of the exciting cause, by which it has been induced, and from the effects of the remedies, which have been employed, as well as from the particular appearances, which the ulcer itself exhibits."

In noticing another ground of distinctions among ulcers, or that derived from the parts in which they occur, Dr. Thomson observes, that "every texture and organ of the body possesses physical and vital qualities peculiar to itself; and these qualities must necessarily modify the appearances, which each texture and organ respectively exhibits in the state of disease. Specific diseases render some parts more liable, than others, to attacks of ulceration. Thus secondary syphilis appears most frequently in the throat; scurvy in the gums; cancer in the lower lip; and lupous and scrophulous ulcerations in the upper lip, or in the nose. Cancer seldom, or never appears primarily in the upper lip; but syphilis, when it attacks this part, puts on many of the appearances of cancer;" a fact, which Dr. Thomson says he first learned from Mr. Pearson. (See *Lectures on Inflammation*, p. 427-430.)

In the valuable treatise on ulcers, published by Sir Everard Home, these complaints are divided into six principal kinds, viz.

1. Ulcers in parts, which have sufficient strength to carry on the actions, necessary for their recovery.
2. Ulcers in parts, which are too weak for that purpose.
3. Ulcers in parts, whose actions are too violent to form healthy granulations, whether this arises from the state of the parts, or of the constitution.
4. Ulcers in parts, whose actions are too indolent, whether this arises from the state of the parts, or of the constitution.
5. Ulcers in parts, which have acquired some specific action, either from a diseased state of the parts, or of the constitution.
6. Ulcers in parts, which are prevented from healing by a varicose state of the superficial veins of the upper part of the limb.

Although I have chosen, in the subsequent columns, to adopt this nomenclature, I am perfectly aware of its being on some accounts objectionable, but, especially, because it assumes hypotheses, the truth of which can never be established, nor proved. This is one of the considerations, which have induced Professor Thomson to prefer the old names usually applied to ulcers; (*Op. cit.* p. 435—438.) and he therefore treats of the *Simple purulent ulcer*;

Inflamed ulcer; *Fungous ulcer*; *Callous ulcer*; *Sloughing ulcer*; *Ulcerative ulcer*; *Carious ulcer*; and *Specific ulcers*.

OF ULCERS IN PARTS, WHICH HAVE SUFFICIENT STRENGTH TO CARRY ON THE ACTIONS NECESSARY FOR THEIR RECOVERY: SIMPLE PURULENT OR HEALTHY ULCERS.

Sir E. Home remarks, that, in this species of ulcer, the pus is of a white colour, thick consistence, and readily separates from the surface of the sore, and when diluted, and examined in a microscope, is found to be made up of small globules, swimming in a transparent fluid. The granulations are small, florid, and pointed at the top. As soon as they have risen to the level of the surrounding skin; those, next to the old skin, become smooth, and are covered with a thin, semi-transparent film, which afterwards becomes opaque, and forms cuticle.

In the treatment of this kind of ulcer, it is only necessary to keep the surface clean, and prevent the natural processes from being interrupted. Sir E. Home observes, that this is in general best done, by the application of dry lint, for the purpose of absorbing and retaining the matter, which serves as a soft covering for the granulations, and by putting over the lint a pledget of any simple ointment, in order to hinder the matter from evaporating; by which means the dressings will not become adherent, and may be easily taken off, as often as requisite.

Although healthy ulcers require no medicated application to be made to them, the dressings must be such as do not disagree with the granulations, or surrounding skin.

With some patients, a roller applied with moderate tightness, with a view of retaining the dressings, will cause uneasiness in the part, and make the ulcer lose its healthy appearance. Sir E. Home states, that he has seen several such cases, in which the proper appearance of the sore returned as soon as the bandage was discontinued.

In some patients, ointment irritates and inflames the neighbouring skin; and certain superficial ulcers will not heal, while kept in a moist state, and unexposed to the air; but heal, when allowed to become dry and covered with a scab.

Sir E. Home refers these particularities to constitutional causes, and not disease; for, the ulcers heal as soon as the particular things, which disagree with them, are discontinued. These peculiarities in certain healthy sores may also attend others of a different description, and should always be discriminated from the effects of disease.

Sir E. Home very judiciously recom-

mends enquiring of patients, who have previously had sores, what kind of applications they derived most benefit from, and what dressings were found to disagree.

TREATMENT.

1. Applications in the form of vapour, and fomentations, should never be employed, as they render the texture of the granulations looser, and diminish the disposition to form skin.

2. With respect to fluid applications, Sir E. Home also very properly condemns poultices, as well as fomentations. He speaks of alcohol, as being an application, which promotes the formation of a scab, when this mode of cure is chosen.

3. In regard to ointments, their only use, in cases of healthy ulcers, is to keep the matter from evaporating. The most simple ointments are the best for the purpose; particularly the one composed of white wax and olive oil.

Sir E. Home observes, that the great objections to the common simple ointments are, that they sometimes disagree with the skin, even when recent, and free from all rancidity. When they have acquired the latter quality, they still more frequently create a greater degree of irritation.

4. With respect to applications in the form of powder, Sir E. Home remarks, that, when it is desirable to form a scab on the ulcer, any inert powder may be sprinkled on the sore; but, he prefers dry lint. Nothing should touch the powder, or lint, and, to prevent this circumstance, Sir E. Home recommends applying a little bolster on each side of the sore, and over them a roller, which will go from one bolster to the other, in the manner of a bridge.

For healthy ulcers, dry lint is to be regarded as being, upon the whole, the most eligible application. When the sore does not secrete pus enough in twenty-four hours to moisten the lint, the dressings are only to be changed every other day.

When a moderately tight bandage is not forbidden by constitutional peculiarities, it is useful, both in supporting the muscles and skin, which are often in a flabby state from the unexercised state of the limb, and in defending the newly formed parts. (See *Home on Ulcers*.)

ULCERS IN PARTS WHICH ARE TOO WEAK TO CARRY ON THE ACTIONS NECESSARY FOR THEIR RECOVERY: THE OVERACTING ULCERS OF MR. BURNS; THE FUNGUS ULCERS OF OLDER WRITERS.

This is the second of the classes, into which Sir Everard Home has divided ulcers in general.

The granulations of these sores are larger, more round on their external surface, and of a less compact texture, than those formed on ulcers in healthy parts. Sir E. Home has also noticed their semi-transparent appearance. When they have filled up the cavity of an ulcer to a level with the surface of the body, they do not readily form skin, but, rising up in a still higher manner, often lose altogether the power of producing new cutis. When the parts are still weaker, the granulations sometimes continue gradually to fill up the hollow of the ulcer, and then, all on a sudden, are suddenly absorbed, so as to leave the sore as deep as it was before.

Ulcers may be weak from the first, or become so in the progress of the case. Even granulations of the most healthy kind, if they are not skinned over in a certain time, gradually lose their primitive strength.

Sores on the legs are greatly under the influence of all natural peculiarities of the constitution, and every thing, which affects the health. When the constitution becomes in the least weaker or stronger, the appearance of the granulation becomes changed accordingly, and this effect of constitutional weakness, or strength, on ulcers is greater, in proportion as the sores are further from the source of the circulation.

While the constitution is undergoing any kind of disturbance, the healing of an ulcer is suspended. Mental anxiety is very apt to retard cicatrization.

Such effects of the constitutional kind on ulcers are greater in weak and delicate persons, than in the strong and robust. Change of weather has considerable influence over the healing of sores. Sir E. Home mentions, in proof of this fact, that when there were several hundreds of ulcers in the Naval Hospital at Plymouth, in 1778, every time the weather changed, from a dry to a moist state, the ulcers universally assumed an unhealthy appearance; but, put on a better aspect, when the weather became dry again.

In the treatment of this kind of ulcer, tonics are to be exhibited, particularly, bark and steel, and every thing which disagrees with the constitution is to be avoided. Wine and cordial medicines are also usually prescribed. Porter, however, is deemed better, than wine, for working people.

Sir E. Home observes, that the first object in the local part of the treatment, is to keep the granulations from rising above the edge of the surrounding skin. This gentleman (in my opinion) very judiciously represents the greater propriety of preventing the granulations from ever becoming

too high by the employment of proper applications, than following the common plan of destroying the high granulations with escharotics, after they have risen to an improper height. There cannot be the smallest doubt, that if the granulations could always be prevented from rising up too much, the patient would suffer a great deal less pain.

Instead of applying to the surface of the ulcers, now under consideration, lunar caustic, blue vitriol, red precipitate, &c. Sir E. Home prefers mixing these escharotics with other substances, so as to render them only strong stimulants, and using them in this latter form. He conceives, that, when the high granulations are destroyed with escharotics, the disposition of the surface underneath to reproduce them is increased, but, that this is not the case, when the luxuriant parts are only stimulated, so as to become absorbed.

The same gentleman seems to think, that, when animal substances grow with great rapidity, they are, like vegetable ones, weaker, than when produced in a slower manner. Hence, Sir E. Home is of opinion, that the growth of granulations ought to be checked in the early stage of their formation, by some resistance, which they are just able to overcome, under which circumstances, they derive strength from the limited increase of action, which they are obliged to undergo.

On the same principle, according to Sir E. Home, the pressure of tight bandages is advantageous, and ulcers, which heal, while the patient is walking about, are not so apt to break out again as they are when healed, while the parts are in a state of perfect rest.

In the treatment of these ulcers, when the granulations have come to a proper height, and do not form a thin, semi-transparent pellicle upon their surface, they are to be considered as weak parts, and treated accordingly. Sir E. Home thinks, that, in this circumstance, the best plan, when no particularity of constitution forbids, is pressure, made with a thin piece of lead over the dressings, and supported with a tight bandage.

OF APPLICATIONS TO ULCERS ATTENDED WITH WEAKNESS.

Although, strictly, we have no topical applications, which can directly communicate strength to granulations, there are certainly some, which prevent the granulations from exhausting themselves by luxuriant growth, and stimulate them to draw more blood from the arteries; which effects, as Sir E. Home remarks, render such granulations stronger.

1. This gentleman very properly con-

demns, as applications to weak ulcers, all relaxing fomentations commonly employed; and recommends, instead of them, the use of spirits of wine and the decoction of poppies, in equal proportions, not, however, to be applied hot.

2. With regard to moist applications, the same gentleman expresses his disapprobation of poultices, and mentions a weak solution of the *argentum nitratum*, as the most eligible application in an aqueous form.

3. On the subject of powdered substances, as applications to weak ulcers, Sir E. Home says, he has often tried bark, and the *lapis calaminaris*, without perceiving, that the former had any power of strengthening granulations, or the latter any virtue in disposing them to form new skin; properties commonly imputed to these applications.

Sir E. Home entertains no better opinion of plaster of Paris, or powdered chalk, employed with a view of promoting the formation of skin. Powdered carbon, he speaks of, as being more adapted to irritable, than weak ulcers. He praises powdered rhubarb, as particularly applicable to the latter kind of ulcer, because, it represses the luxuriant growth of the granulations, renders them small and compact, and disposes them to form skin. When, however, the granulations have risen above the level of the skin, it is not powerful enough to reduce them. When the rhubarb is too stimulating, it is to be mixed with a fourth part of crude opium in powder.

A piece of lint, a little less than the sore, is always to be put over the powder, and covered with a pledget of simple ointment.

4. Ointments, according to Sir E. Home, are particularly apt to disagree with weak ulcers. When other applications fail, however, greasy ones may be tried, and the above gentleman gives a preference to the *ung. hydrarg. nitrat.* mixed with hog's lard, in the proportion of one to five, or else to common cerate, blended with a small quantity of the *hydrarg. nitrat. ruber*.

OF ULCERS IN PARTS, WHOSE ACTIONS ARE TOO VIOLENT TO FORM HEALTHY GRANULATIONS; EITHER FROM THE STATE OF THE PARTS, OR THE CONSTITUTION: SIMPLE VITIATED ULCERS OF MR. B. BELL.

There are three states of the constitution influencing the nature of ulcers: an irritable state, in which all the actions of the animal economy are more rapid, than in health; an indolent state, in which they are unusually languid; and, lastly, a diseased state, by which they are affected.

An irritable, and an indolent ulcer can-

not in general be distinguished from each other by mere appearances, though they may be so in a few instances. Sir E. Home informs us, that the disposition of an ulcer, like the disposition of a constitution, can only be accurately ascertained by determining the actions, which arise from the different impressions made upon it.

The same gentleman notices, that the following appearances at once shew the ulcer to be of an irritable kind. The margin of the surrounding skin being jagged, and terminating in an edge, which is sharp and undermined. The bottom of the ulcers being made up of concavities of different sizes. There being no distinct appearance of granulations, but, a whitish spongy substance, covered with a thin, ichorous discharge. Every thing, that touches the surface, gives pain, and very commonly makes it bleed. The discharge is altered from common pus to a thin fluid, in proportion to the degree of irritability communicated to the sore by constitutional causes.

The pain of an irritable sore in general gradually becomes less. When it is not constant, but comes on in paroxysms chiefly in the evening, or night-time, with great violence, convulsive motions of the limb are apt to occur, and extend to various other parts. Sir E. Home refers this symptom to irritation communicated along the course of the nerves, and producing an action in them, attended with a violent contraction of the muscles, which they supply.

When the above-mentioned signs of an irritable ulcer are not present, we must form a judgment of the nature of the sore from listening to the history of the case, the effects of various applications, &c. When this kind of information cannot be obtained, Sir E. Home recommends the treatment to begin on the supposition of the ulcer being of an irritable nature.

When an ulcer occurs just over the malleolus externus, it is generally of an irritable kind, in consequence of the nature of the part, on which it is situated, quite independently of any constitutional, or local disposition to irritability. Sir E. Home conceives, that the periosteum, which here lies immediately under the skin, becomes the seat of the ulcer, is the cause of its being very difficult to heal, and gives it the irritable appearance. The fact, that sores, situated on the ligament of the patella and over the periosteum of the anterior surface of the tibia, assume a similar appearance, and are equally difficult to heal, made the above gentleman more confirmed in his sentiment.

In treating ulcers in general, the surgeon will find it exceedingly advantageous to be acquainted with the effects of a

great many different external applications; for, a very few cases will continue to heal beyond a certain time, without some alteration in the treatment. The necessity of changing the applications, after they have been continued for a certain time, is strikingly illustrated by the fact, that leaving off a powerful application, and employing one, which at first would have had no effect, often does a great deal of service. When the change is made to a medicine of powers equal to those of the previous one, the benefit will be more lasting, than in the preceding circumstance.

Sir E. Home compares the principle of this occurrence, with that, by which change of air, even of a very salubrious air, for one that is less so, often produces an infinite improvement of the health.

OF APPLICATIONS TO IRRITABLE ULCERS.

1. Sir E. Home recommends applications, in the form of vapour, as being particularly useful, by their quality of allaying irritation, and soothing pain.

The steam of warm water is productive of benefit in this way, though seldom used by itself. Its good effects are increased, when it is mixed with spirits.

Sir E. Home speaks also in favour of the benefit derived from fomentations containing opium; such as, the tincture of opium sprinkled on flannel, wrung out of hot water; or the application of flannels, wet with a warm solution of the extract of opium, or with a decoction of poppy heads. A decoction of chamomile flowers, the tops of wormwood, or hemlock leaves, may also be employed for the same purpose.

Sir E. Home points out particular irritable ulcers, however, which are rendered more painful by warm applications, and he states, that, the sores, alluded to, are generally attended with a mottled purple discoloration of the limb, for some way from them, and a coldness of the lower part of the leg, and that they are often disposed to mortify, which event is promoted by warmth.

2. As for moist applications, the poultice made of linseed meal is the most simple and most easily made, and, as it does not necessarily require any addition of oil, is to be preferred, when this disagrees with the sore.

Sir E. Home does not say much in favour of the use of the extract of lead in poultices; for, though he allows, that it often answers very well, he adds, that it also frequently disagrees with the ulcer, and, if long used, is apt to bring on the lead-colic.

A decoction of poppy-heads is said to be a very good liquor for making poultices.

The carrot-poultice is also found to agree with a great many irritable sores.

The great objection to poultices, in these cases, being the weight of such applications, the limb should always, if possible, rest upon the poultice, and not the poultice upon the limb. When the weight cannot be avoided, and is hurtful, a lighter application should be chosen.

If poultices be employed, their use is to be continued, as long as the granulations are small, and the ulcer is rapidly diminishing in size, and this even till the cicatrization is complete. When the granulations become large, and loose in their texture, poultices should be left off.

When the weight of poultices prohibits their use, Sir E. Home advises the trial of lint, dipped in one of the following lotions, and covered with a pledget of some simple ointment: a solution of the extract of opium; a decoction of poppies; the tincture of opium; a decoction of cicuta; the aqua lithargyri acetati composita; or a diluted solution of the argenti nitratum.

3. Powdered applications are generally too stimulating for irritable ulcers. Carbon has been found useful; so has powdered extract of opium, mixed with an equal quantity of carbon, or linseed flour. However, opium occasionally affects the constitution, in consequence of absorption, and it has been known to excite violent inflammation, ending in mortification.

4. Ointments are not often proper applications for irritable ulcers; as they are always, more or less, rancid, and generally disagree with the skin of persons, most subject to such diseases.

Sir E. Home mentions cream as being a very useful application, particularly in cases, in which warmth is found to do harm. The same gentleman recommends, as a substitute for it, an ointment, composed of hog's lard, purified by being repeatedly washed in spring water, and then mixed with a small quantity of white wax, and rose water.

The observations, made respecting solutions of lead, apply to the unguentum cerussæ acetatæ.

5. The pressure of bandages is generally hurtful to irritable sores, though a slight degree of it proves serviceable to certain ulcers, which are somewhat less irritable, and arise from weakness.

OF ULCERS IN PARTS, WHOSE ACTIONS ARE TOO INDOLENT TO FORM HEALTHY GRANULATIONS, WHETHER THIS INDOLENCE ARISES FROM THE STATE OF THE PARTS, OR OF THE CONSTITUTION: THE CALLOUS ULCERS OF SEVERAL WRITERS.

Such is the next division of ulcers adopted by Sir E. Home in his treatise on

the subject. The indolent ulcer forms in its appearance a complete contrast to the irritable one. The edges of the surrounding skin are thick, prominent, smooth, and rounded. The surface of the granulations is smooth and glossy. The pus, instead of being of a perfect kind, is thin and watery, being composed of a mixture of pus and coagulating lymph. The lymph consists of flakes, which cannot be easily separated from the surface of the sore. The bottom of the ulcer forms quite a level, or nearly so, and, as Sir E. Home very accurately remarks, the general aspect conveys an idea, that, a portion of the skin and parts underneath has been for some time removed, without the exposed surface having begun any new action to fill up the cavity.

When, however, the indolence of the ulcer is not so strongly marked, the sore does not correspond to the preceding description, but resembles in appearance the ulcer, which possesses an inferior degree of irritability, and can only be discriminated from it by receiving no benefit from soothing applications.

The odd circumstance of some indolent sores having the appearance of irritable ones, is, in some degree, explained by ulcers always being influenced by changes in the constitution, and accidental circumstances affecting the parts.

Most of the ulcers, which are to be seen in the London hospitals, are of the indolent kind. An indolent disposition in the ulcer may proceed altogether from the long existence of the disease, and, hence, Sir E. Home very justly observes, it is immaterial, whether at first it was healthy, weak, or irritable, for, if not cured within a certain time, it becomes indolent, with the exception of a few of the irritable kind, which never change their nature.

Indolent sores do form granulations; but, these, every now and then, are all on a sudden absorbed, and, in the course of four and twenty hours, the sore becomes as much increased in size, as it had been diminished in as many days, or weeks. This absorption of the granulations arises principally from their not being of a healthy kind; but, the event is promoted by changes in the weather, anxiety, fatigue, &c.

The object in the treatment of indolent ulcers is not simply to produce a cure, but to render such cure as permanent as possible. This can only be accomplished by altering the disposition of the granulations, and rendering them strong enough to stand their ground after the ulcer is filled up.

When an ulcer, which has existed six months, is dressed with poultices for a week, the granulations, at the end of this time, will have in part filled up the hollow

of the sore, but they will present a large, loose, and glossy appearance. Should the poultice be now discontinued, and some proper stimulating application used for another week, the granulations will be found, at the expiration of this time, to have become smaller, more compact, redder, and free from the glossy appearance. The ulcer, when healed by the latter application, will not be so likely to break out again, as when healed with large, loose, flabby, glossy granulations.

Sir E. Home states, that the number of indolent sores, which heal under the use of stimulating applications, and do not break out again, compared with similar cases, treated with mild dressings, are as four to one.

APPLICATIONS TO INDOLENT ULCERS.

1. Medicines in the form of vapour cannot heal indolent sores, so as to accomplish a lasting cure. It is only when these ulcers assume a foul appearance, and are in a temporary state of irritation, that such applications can be advantageously employed.

In general, patients on their first admission into hospitals with sore legs, have their ulcers in a temporary state of irritation from neglect, exercise, excesses, &c. Hence, it is generally found advantageous, for the first few days, or even a week, to have recourse to poultices and fomentations.

I believe, that any common fomentation, whether of chamomile, poppy-heads, or mere warm water, answers equally well. The time for using it, is while a fresh poultice is preparing, and this latter application should be changed twice a day.

2. Moist applications, such as poultices, are to be employed, when fomentations are proper, and they may be made of bread, oatmeal, or linseed.

Sir E. Home describes a species of indolent ulcers, which occur in patients of debilitated constitutions, which put on a sphacelated appearance, without any apparent cause, even after they have made some progress towards a cure, and in this way spread to a very large size. Some of these ulcers, if judged of from their appearances, would be ranked as irritable ones; but, as soothing applications do not agree with them, they are not to be classed with the latter kind of sores. They are said to occur particularly in seamen, and soldiers, who have been long at sea, and have been termed *scorbutic* ulcers. Sir E. Home represents them, however, as not being necessarily connected with the scurvy, and being often met with in patients, who have not been on the sea. This gentleman states, that these ulcers

are not of necessity joined with any specific disease; but are common to all kinds of patients, whose constitutions have been impaired, either by salt provisions, warm climates, or drinking.

From some trials, first made by Dr. Harness, and afterwards by Sir E. Home, it appears, that these particular ulcers, when in a sphacelated state, are benefited by employing the gastric juice of ruminating animals, as an external application. It makes the sloughs fall off, and the sore assume a better appearance. Some pain follows on its being first applied, and it is to be regarded as a stimulating application.

Sir E. Home mentions, that in the West Indies, such ulcers are advantageously dressed with the fresh root of the cassada, grated into a pulp. Lime-juice has also been found a useful application, and solutions of vitriol and alum have been recommended.

When indolent ulcers are not attended with certain peculiarities, a solution of the *argentum nitratum* is one of the best of the watery applications. It stimulates the granulations, and makes them put on a more healthy appearance, and its strength may be increased according to circumstances. An ulcer, which at first cannot bear this solution above a certain strength, without pain, and without the granulations being absorbed, becomes able, after the application has been used, about ten days, or a fortnight, to bear it twice as strong, without such effects being produced: a proof of the granulations having acquired strength.

The tincture of myrrh is often employed as an application to indolent ulcers. Hunezowsky has praised a decoction of the walnut-tree leaves, and soft covering of the walnut, for the same purpose. (*Acta Acad. Med. Chir. Vindob. Tom. 1. 1788.*) Sir E. Home gives his testimony in favour of both the latter dressings.

The diluted vitriolic acid, and the expressed juice of the pod of different species of pepper in a recent state, are mentioned by Sir E. Home as having been used as applications to indolent ulcers: the latter one in the West Indies.

This gentleman recommends also a scruple of nitrous acid, mixed with eight ounces of water, as a very useful medicine for external use. The strength must be increased or diminished, according to circumstances. Sir E. Home has found, that this application promotes, in a very uncommon manner, the progress of the cure.

The first application of diluted nitrous acid gives a good deal of pain, which lasts about half an hour, and then goes off.

When an indolent ulcer heals with the diluted nitrous acid, the process of skinning is accomplished with more rapidity,

than when other applications are employed; and the new skin is said to be more completely formed. The acid coagulates the pus as soon as it is secreted.

Sir E. Home states, that several patients, who had ulcers dressed with the diluted nitrous acid, were allowed to walk about, without finding the progress of the cure retarded, although no bandage to support the limb was made use of. This gentleman informs us, also, that in ulcers of the leg, attended with an exposure of a piece of bone, which retards the cure, because it does not exfoliate, and come away, the application of diluted nitrous acid to the bone removes the earthy part, and excites the absorbents to act upon the remaining animal portion.

3. The only application, in the form of powder, adapted to indolent ulcers, is, according to Sir E. Home, the *hydrargyrus nitratus ruber*. It is only to be occasionally used for ulcers of the most indolent kind.

4. Ointments are represented as being particularly proper applications for the sores under consideration.

The idea of the air having bad effects on ulcers exposed to it, is now disbelieved. That air has no irritating property of this kind, is proved by the fact, that, when the abdomen of an animal is filled with it, no inflammation is excited. When the cellular membrane is loaded with it, in cases of emphysema, the parts do not afterwards inflame. Nor do ulcers in the throat, as Sir E. Home justly remarks, heal less favourably than others, although they are of necessity always exposed to the air.

Whatever ill effects arise, may probably be explained by the consequences of evaporation, which converts the soft pus into a scab. The granulations are, in all probability, most favourably circumstanced, when they are covered with their own matter, which should only be now and then removed, in order that such applications may be made, as will stimulate them to secrete a more perfect pus. From what has been just stated, it must be obvious, that indolent ulcers should not be frequently dressed, and, that if they are so, and the dressings are stimulating, the practice will do harm. Changing the dressings once in twenty-four hours is deemed quite sufficient, unless the quantity of matter is very great, which very seldom happens in these cases.

One part of the *unguentum hydrargyri nitrati* mixed with three of hog's lard, is one of the best applications. Its strength, however, must be increased after being used, for some time, as a dressing for the same ulcer.

The *unguentum hydrargyri nitrati* has the effect of quickly removing the thick-

ening of the edges of indolent ulcers, and the surrounding dark red colour of the skin. It seems also to have particularly great power in making the granulations become small and healthy, and, of course, the ulcer is less likely to break out again.

With some ulcers, however, this ointment is found to disagree.

The *unguentum resinæ flavæ*, and the *unguentum elemi*, mixed with the balsam of turpentine, or that of copaiba, are other common applications to indolent sores. Sir E. Home states, that the resins and turpentine are not so powerful, as the acids and metallic salts, in giving the granulations a healthy appearance, and a disposition to resist being absorbed.

Cases, attended with a degree of indolent thickening, are such as are most likely to be improved, by camphorated ointments.

In numerous cases, the applications, whatever they are, soon lose their effect, and others should then be substituted for them. The past and present states of the sore are always to be considered. Although the ulcer may be in its nature indolent, it is liable to temporary changes, from constitutional causes, and hence, a temporary alteration in the treatment becomes proper.

5. Bandages are undoubtedly of the most essential service in healing many kinds of ulcers: but, their efficacy is so great in curing numerous indolent sores, that they are considered by some as the principal means of cure.

Among the advocates for the employment of the roller, Mr. Whately is one of the most zealous. The following extracts will convey to the reader a tolerably good idea of this gentleman's opinions.

"The efficacy of pressure in counteracting the effects of the dependant posture, was indeed known to the father of English surgery; and the use of the laced stocking was recommended by him for this purpose; nor can there be any doubt, that, the good effects of it, in his hands, were very manifest. His ideas, however, seem not to have been much regarded by succeeding surgeons. We find but little said by the writers on surgery, on the effects of pressure in the cure of ulcers on the lower extremities, previous to the appearance of Dr. Underwood's treatise. Yet I am aware, that there always have been practitioners, who were acquainted with the importance of this mode of treatment, and have adopted it in their practice. I had, myself, an opportunity of seeing the extraordinary success attending it, during my apprenticeship in the country. It is matter of fact, however, that the practice is very far from being general. Even in one of the latest publications on the subject, and this too by a surgeon of

the first eminence, the effect of pressure is not much relied upon for the cure of these complaints. It is, indeed, there stated, in several passages, not only that no benefit is derived from compression in several species of these ulcers, but that many ulcers are rendered worse, more painful, and more unhealthy in their appearance by its use (as observed in Sir Everard Home's Remarks on Ulcers of the Legs.) That there are certain conditions of an ulcer, which will not bear compression, I have allowed, and have endeavoured to point out the proper treatment, to bring on a fit state for the application of that pressure: but that an experienced surgeon should pass over so slightly this most essential part of the cure, and even speak of it as *frequently* injurious, is a circumstance hardly to be attributed to any other cause than that of a careless and ineffectual application of the bandages. For my own part, having now been for twenty years constantly in the habit of treating a very large number of these cases, I can speak so confidently of the good effects of pressure, properly applied, that I can venture to affirm, that he who doubts its efficacy, has never given it a fair trial.

"In the cases which are added to this essay, (says Mr. Whately) very little variety of dressing was used; the cure was almost always trusted principally to the pressure made on the limb, under the exceptions particularly specified in the work. My success has been so uniform, that I cannot but be anxious to see this practice become established and generally followed. Nothing but a conviction, that in promoting this end, I am really doing an important service to my fellow-creatures, could have induced me to appear before the tribunal of the public, conscious as I am of my incompetency as a writer. But may I not hope, that the plain tale of a practical man will be heard, though not told with the graces of elegant language?

"In whatever manner this attempt be received, I cannot doubt but that the practice here recommended must, in the end, prevail, notwithstanding it has this great obstacle to contend with, that surgeons must condescend, for the most part, to apply the bandages with their own hands. The clumsy and ineffectual manner, in which this business is too frequently done, can never be expected to produce the desired effect. I am certain, that if the necessary pains be taken, according to the directions here laid down, such effects will uniformly follow, as must convince the unprejudiced mind, that to have recourse to the operation of tying varicose veins, and the application of a great variety of remedies, can be *very*

rarely, most probably *never* necessary. I can safely declare, that all such cases, as are described by Sir E. Home to be cured by this operation, have readily yielded, under the proper management of pressure alone.

"Since these papers were preparing for the press, I have seen with pleasure Mr. Baynton's new method of treating these complaints. Every thing that is there said on the efficacy of his method, may be considered as confirming the doctrine laid down in the following pages. His mode, however, of making the pressure with adhesive plaster, appears to me inconvenient, and on several accounts objectionable. I have no doubt but that the proper application of compresses and flannel rollers, would, in every case recorded by him, have produced similar good effects. The instances of success by this method, after the supposed failure by the roller, I can only attribute to this, that the pressure made with the plasters was applied by his own hands, whereas that with the roller, was probably, as is usual, so made, that the effect intended by it could not possibly have been obtained. No surgeon, who will not be at the trouble of applying them himself, can be a judge of what may be effected, by the proper management of the roller and compresses."

The following is the calamine cerate, which Mr. Whately has usually employed:

R_x. Axung. Porcin. depur. lib. iij.

Empl. Lithargyr. lib. iss.

Lap. Calam. præp. ap. lib. j. M.

"To this formula (says Mr. Whately) I shall add another for making a cerate, which nearly resembles the unguentum tripharmicum of the old Dispensatory, but being less oily, it makes a much more adhesive plaster. It should be spread on rag, or silk, as an external covering to the dressing on lint, where a tow plaster cannot be conveniently used; as in wounds of the face or hands, a bubo, or any other sore, where an external plaster cannot be readily retained in its situation by a bandage. This plaster is likewise so mild, that it never irritates the skin. I have found it also a very useful plaster in fractures. The following is the formula:

R_x. Empl. Litharg. lib. j.

Axung. Porcin. depur. unc. vj.

Aceti unc. iv. M."

With respect to the proper method of applying the roller and compresses, Mr. Whately offers the following remarks:

"I have said, that the flannel rollers should be four inches wide, to allow for shrinking in washing; by which I would have it understood, that when they are made of that width, they are a little too wide: especially for those whose legs are small. The best width for a flannel roller,

designed for those who have slender legs, is three inches; but for those, whose legs are of a large size, they should always be three inches and a half in width. They must therefore be at first torn a little wider, that they may be of their proper width when repeatedly washed. It will likewise be found, that rollers made of fine, soft, and open flannel, will answer much better, than those made of coarse or hard flannel.

"For those who have full sized legs, the length of six yards is but just sufficient to answer all the purposes intended by a roller; but in those who have very small legs, five yards is a sufficient length. Care should be taken that the rollers be washed in very hot water, and they should be hung up to dry immediately on being washed. If these precautions be not attended to, repeated washing them will, in some kinds of flannel, make them as narrow as tape, by which they will be rendered almost useless. They should be often washed, as they are much softer, and of course sit easier, when quite clean, than when they are soiled.

"In applying a roller, (says this gentleman,) the first circle should be made round the lowest part of the ankle, as near as possible to the heel; the second should be formed from thence round the foot; the third should be passed again round the foot quite to the toes. The roller should then be passed from the foot round the ankle and instep a second time to make the fourth circle. In doing this, it should be brought nearer (but not over) the point of the heel than it was at the first time of going round this part. The fifth circle should pass over the ankles again, and not more than half an inch higher up the leg than the fourth circle. The sixth, seventh, eighth, and ninth circles should ascend spirally along the small of the leg, at the exact distance of three-fourths of an inch from each other. Having proceeded thus far up the leg, we may begin to increase the distances of the circles from each other; they may succeed each other upward to the knee at the distance of from one to two inches, according to the size and shape of the leg. At that part where the calf of the leg commences, it is generally necessary to let the upper edge of the roller be once, twice, or thrice, turned downwards for about half the circumference of the leg, in order to make the roller lay smooth between the middle of the calf, and the small of the leg. When the roller has been thus applied as far as the knee, there will be a portion of it to spare, of perhaps a yard in length; this remainder should be brought down by spiral windings, at greater distances from each other than those which were made on the ascent of the roller. The windings

should in general be completed in the small of the leg, where the roller should be pinned.

"In many cases, it is necessary to apply the roller over the heel. It should be brought as low as possible round the ankle; as in the former description. From thence, the second circle of the roller should pass from the instep over one side of the heel, and be brought over the other side of the heel to the instep again. The third circle should be passed round the ankle a second time, but still nearer to the heel than the first circle was. The roller should after this be brought back to the foot, and passed round it to make the fourth circle. A fifth circle should be again made (though it is not in all cases absolutely necessary) round the foot, to the toes. To make the sixth circle, the roller should be brought back, and passed round the ankle again. The seventh, eighth, ninth, tenth, and eleventh circles should ascend spirally at the exact distance of three-fourths of an inch from each other; these distances commencing at the sixth circle. The roller should then be carried to the knee, and be brought down again to the small of the leg, as described in the former instruction.

"In applying the compresses, it is necessary in every instance to put them on one by one, and not all in a mass, though they be of a proper size and number. They should be crossed in different directions; the largest of them should in no case be longer than just to meet on the opposite side of the leg, to which they are applied. I have in many instances seen the compresses applied by the patients of such a length as to go round the leg like a roller, and be fastened together with pins. This method generally wrinkles and blisters the skin, and by no means answers the purpose of making a compression on the part where it is most wanted. I never suffer a pin to be used in the compresses. If the same compresses in any case be applied two days together, they should always be turned on the contrary side at each re-application, in order to prevent wrinkles on the skin."

Mr. Whately notices two objections made by Mr. Baynton to rollers. "The first is, that it is difficult to retain the roller on the parts to which it is applied; the second is, that it gives pain to the patient." Mr. Whately's experience, however, warrants him in saying, that a flannel roller will, in almost every instance, keep the exact position it was first placed in, for a much longer time than is necessary. "I have seen these rollers (says Mr. Whately) many hundred times keep their situations without any variation whatever for two days; and that too without the least restraint upon exercise. This has hap-

pened in those cases, where from the distance of the patient, or from the circumstance of his being nearly cured, I have wished to dress the leg only every forty-eight hours. I must go a step further, and observe, that I have seen repeated instances in which these rollers have remained in their situation for three or four days, and even nearly for a week without being applied afresh. In short, it is one of the best properties of a flannel roller, that it is easily retained in its situation, when well applied. In every instance, in which it is necessary to use one, I could pledge myself to apply it in such a manner, as should prevent its altering its position for two days. The method I should use, I have already described; in addition to which, nothing more would be necessary, even in those cases where the shape of the leg is peculiarly unfavourable to the retention of a bandage, than the insertion of a few pins.

"In answer to the second objection, I observe, that I have invariably found, that when a flannel roller has been applied in the manner here described, and has not been drawn unnecessarily tight, it gives no pain. It sits nearly as easy as a common stocking, and allows a very free motion and exercise of the limb. It has been stated in this work, that the application of the compresses makes the necessary degree of pressure on the ulcer, and thereby prevents the necessity of drawing the roller so tight over the other parts of the leg, as would have been necessary were the compresses not used.

"There is another circumstance which Mr. Baynton considers as giving his method a great advantage over the roller, which is, that by means of the plaster, the edges of the sore may be made to approximate in such a manner, that the cicatrix, or new-formed skin, will be less after a cure performed by this method than by any other. In almost all these cases, before the cure is attempted, the leg is more or less enlarged by swelling; and as this swelling is entirely removed by compression, it readily allows the skin to approximate on the healing of an ulcer. Added to this, there is a process in nature always going on in healing an ulcer or wound in any part of the body, (whether there be a loss of substance or not,) by which a cicatrix is always considerably less than the previous size of the sore. This effect occurs in all cases, whether the patient be cured by the horizontal position, a roller, or by strips of adhesive plaster. The size of this cicatrix will likewise vary in different cases where the ulcers have been of the same size, by whichever of these three methods they be cured. It will be larger in those ulcers which are accompanied with strong adhe-

sions of the adjoining parts, than in those where such adhesions have not been produced; and this effect will take place to the greatest degree where the ulcers are situated over the tibia, and by long continuance have produced immoveable adhesions of the cellular substance to the adjoining periosteum. The adhesive plaster, when applied as a bandage, will without doubt leave as small a cicatrix as any other method of cure; but, for the reasons already assigned, I do not believe that the cicatrix will in any case be smaller than that produced by a roller. In every case cured by the latter method, I have found the cicatrix very small, when compared with the previous size of the ulcer."—(See *Practical Observations on the Cure of Wounds and Ulcers on the Legs, without Rest*; by Thomas Whately, 1799.)

6. We shall next introduce an account of Mr. Baynton's plan of curing old ulcers of the leg, by means of adhesive plaster. Were I to say, that any particular method of dressing such sores is entitled to superior praise, I should certainly decide in favour of this gentleman's practice. I have seen it most successful myself, and I hear it highly spoken of by numerous professional friends, in whose unprejudiced judgment I place much reliance.

Mr. Baynton acquaints us, that the means proposed by him will, in most instances, be found sufficient to accomplish cures in the worst cases, without pain or confinement. After having been repeatedly disappointed in the cure of old ulcers, Mr. Baynton determined on bringing the edges of old ulcers nearer together by means of slips of adhesive plasters. To this he was chiefly led, from having frequently observed, that the probability of an ulcer continuing sound, depended much on the size of the cicatrix, which remained after the cure appeared to be accomplished; and from well knowing, that the true skin was a much more substantial support and defence, as well as a better covering, than the frail one, which is obtained by the assistance of art. But, when he had recourse to the adhesive plaster, with a view to lessen the probability of those ulcers breaking out again, he little expected, that an application so simple would prove the easiest, most efficacious, and most agreeable means of treating ulcers.

Although the first cases, in which Mr. Baynton tried this practice, were of an unfavourable nature, yet he had soon the satisfaction to perceive that it occasioned very little pain, and materially accelerated the cure, while the size of the cicatrices were much less than they would have been, had the cures been obtained by any of the common methods.

At first, however, the success was not quite perfect; as, in many instances, he

was not able to remove the slips of plaster, without removing some portion of the adjacent skin, which, by occasioning a new wound, proved a disagreeable circumstance, in a part so disposed to inflame and ulcerate, as that in the vicinity of an old sore. He therefore endeavoured to obviate that inconvenience by keeping the plasters and bandages well moistened with spring-water, for some time, before they were removed from the limb. He had soon the satisfaction to observe, that the inconvenience was not only prevented, but that every succeeding case justified the confidence he now began to place in the remedy. He also discovered, that moistening the bandages was attended with advantages which he did not expect: while the parts were wet and cool, the patients were much more comfortable in their sensations, and the surrounding inflammation was sooner removed, than he had before observed it to be.

By the mode of treatment here recommended, Mr. Baynton found, that the discharge was lessened, the offensive smell removed, and the pain abated in a very short time. But, besides these advantages, he also found, that the callous edges were in a few days level with the surface of the sore; that the growth of fungus was prevented, and the necessity of applying painful escharotics much lessened, if not entirely done away. Mr. Baynton gives the following description of his method.

"The parts should be first cleared of the hair, sometimes found in considerable quantities upon the legs, by means of a razor, that none of the discharges, by being retained, may become acrid, and inflame the skin, and that the dressings may be removed with ease at each time of their renewal, which, in some cases, where the discharges are very profuse, and the ulcers very irritable, may, perhaps, be necessary twice in the twenty-four hours, but which I have, in every instance, been only under the necessity of performing once in that space of time.

"The plaster should be prepared by slowly melting, in an iron ladle, a sufficient quantity of litharge plaster, or diachylon, which if too brittle, when cold, to adhere, may be rendered adhesive by melting half a drachm of resin with every ounce of the plaster: when melted, it should be stirred till it begins to cool, and then spread thinly upon slips of smooth porous calico, of a convenient length and breadth, by sweeping it quickly from the end, held by the left hand of the person who spreads it, to the other, held firmly by another person, with the common elastic spatula used by apothecaries; the uneven edges must be taken off, and the pieces cut into slips, about two inches in breadth, and of a length that will, after being passed round

the limb, leave an end of about four or five inches. The middle of the piece so prepared, is to be applied to the sound part of the limb, opposite to the inferior part of the ulcer, so that the lower edge of the plaster may be placed about an inch below the lower edge of the sore, and the ends drawn over the ulcer with as much gradual extension as the patient can well bear; other slips are to be secured in the same way, each above and in contact with the other, until the whole surface of the sore and the limb are completely covered, at least one inch below and two or three above the diseased part.

"The whole of the leg should then be equally defended with pieces of soft calico, three or four times doubled, and a bandage of the same, about three inches in breadth, and four or five yards in length, or rather, as much as will be sufficient to support the limb from the toes to the knee, should be applied as smoothly as can be possibly performed by the surgeon, and with as much firmness as can be borne by the patient, being first passed round the leg, at the ankle joint, then as many times round the foot as will cover and support every part of it, except the toes, and afterwards up the limb till it reaches the knee, observing that each turn of the bandage should have its lower edge so placed as to be about an inch above the lower edge of the fold next below.

"If the parts be much inflamed, or the discharge very profuse, they should be well moistened, and kept cool with cold spring-water poured upon them as often as the heat may indicate to be necessary, or, perhaps, at least, once every hour. The patient may take what exercise he pleases, and it will be always found, that an alleviation of his pain and the promotion of his cure will follow as its consequence, though, under other modes of treating the disease, it aggravates the pain, and prevents the cure.

"These means, when it can be made convenient, should be applied soon after rising in the morning, as the legs of persons affected with this disease are then found most free from tumefaction, and the advantages will be greater than when they are applied to limbs, in a swollen state. But at whatever time the applications be made, or in whatever condition the parts be found, I believe it will always happen, that cures may be obtained by these means alone, except in one species of the disease, which seldom occurs, but that will hereafter be described. The first application will sometimes occasion pain, which, however, subsides in a short time, and is felt less sensibly at every succeeding dressing. The force, with which the ends are drawn over the limb, must then be gradually increased, and when the parts are restored

to their natural state of ease and sensibility, which will soon happen, as much may be applied as the calico will bear, or the surgeon can exert; especially if the limb be in that enlarged and incompressible state, which has been denominated the scorbutic, or if the edges of the wound be widely separated from each other."

Mr. Baynton afterwards takes notice of the breaking of the skin, near the ulcers; a circumstance, which sometimes proved troublesome, and arose partly from the mechanical effect of the adhesive plasters, and partly from the irritating quality of the plaster. Mr. Baynton, however, only considers such sores of serious consequence, when they are situated over the tendon of Achilles, in which situation they are sometimes several weeks in getting well. This gentleman recommends, with a view of preventing these ulcers, a small shred of soft leather to be put under the adhesive plaster.

Mr. Baynton next adds, "that cures will be generally obtained without difficulty, by the mere application of the slips and bandage; but, when the parts are much inflamed, and the secretions great, or the season hot, the frequent application of cold water will be found a valuable auxiliary, and may be always safely had recourse to, where the heat of the part is greater, than is natural, and the body free from perspiration." (See *A Descriptive Account of a New Method of Treating Old Ulcers of the Legs*, by Thomas Baynton, Surgeon at Bristol. Edit. 2. 1799.)

One circumstance, strongly in favour of the advantages of the foregoing mode of treatment, deserves particular notice: when M. Roux lately visited the London hospitals, he had for the first time an opportunity of seeing this practice, which had never been tried in France. The plan appeared to him so different from every thing which he had been accustomed to see in his own country, where ulcers were almost always treated by rest in an horizontal posture, and emollient applications, that he left London somewhat prejudiced against the new method. Subsequently to his return to Paris, however, he has given it a fair trial, and experience has now entirely changed his opinion, as he has had the candour to acknowledge. (See *Rélation d'un Voyage fait à Londres en 1814, ou Parallèle de la Chirurgie Angloise avec la Chirurgie Française* par P. J. Roux, p. 150.)

OF ULCERS ATTENDED WITH SOME SPECIFIC DISEASED ACTION, EITHER CONSTITUTIONAL, OR LOCAL.

1. Ulcers which yield to Mercury.

Here we shall exclude from consideration venereal ulcers, as this subject is treated of in the article *Venereal Disease*.

At present, we shall only notice such sores, as are produced by other diseases of the general system, or of the parts, and are capable of being cured by mercury.

Perhaps, there is no greater source of error in the whole practice of surgery, than the supposition, that a sore, when it yields to mercury, must be of a syphilitic nature. Surgeons, however, who run into this absurdity, can hardly be imagined to be unaware, that so potent a medicine must have effects on numerous diseases of very different descriptions. Sir E. Home accurately remarks, that many ulcers, unconnected with the venereal disease, which receive no benefit from other medicines, heal under a mercurial course, or yield to mercurial applications. In some cases, the ulcer remains in the same state, while mercury is used; but, begins to look better, as soon as the medicine is discontinued, in consequence of the beneficial change, produced in the system by the mercurial course. In these cases, mercurial frictions are the best, because they occasion least impairment of the constitution, in consequence of the stomach continuing undisturbed, and capable of digesting well.

Another description of ulcers, noticed by Sir E. Home, as deriving benefit from mercury, occur on the instep and foot, have a very thickened edge, and are attended with a diseased state of the surrounding skin, so as to bear some resemblance to elephantiasis. They are frequently observed affecting servants, who live in opulent families, in an indolent and luxurious way. Sir E. Home states, that fumigations with the hydrargyrus sulphuratus ruber heal these ulcers, and resolve in a great degree the swelling of the surrounding parts. In some instances, an ointment of calomel and hog's lard; in others, the camphorated weak mercurial ointment, is the best application.

Many diseased ulcers, particularly those of a superficial kind, with a thickened edge, may be healed, when they are dressed with a solution of one grain of the hydrargyrus muriatus, in an ounce of water, containing a little spirit.

2. Ulcers, which are curable by Hemlock.

Sir E. Home places more reliance on hemlock, as an external, than an internal remedy, for ulcers. The ulcers, which usually receive benefit from hemlock applications, look like those of an irritable sort; but, the surrounding parts are thickened, in consequence of some diseased action. Such sores occur near the ankle; which joint is at the same time enlarged. Sometimes, but not so often, they take place over the ligaments of the knee. On account of their situation, and the swelling of the joint, they may be suspected to be scrophulous, though they are more sen-

sible, than strumous ulcers usually are. The sores, just described, are rendered less painful, their diseased disposition is checked, and the swelling of the joint diminished, by hemlock. Several irritable scrophulous ulcers are also particularly benefited by this medicine.

Sir E. Home gives the preference to hemlock poultices, unless their weight should be objectionable, in which cases, he advises lint to be dipped in a decoction of the herb, and put on the sore.

Of the ointment, made with the inspissated juice, Sir E. Home says but little, in regard to its efficacy.

3. *Ulcers which may be cured by Salt Water.*

Sir E. Home takes notice of other specific ulcers, which yield to this application, after resisting other remedies. Poultices, made with sea-water, are often employed; but, this gentleman seems to prefer keeping the part immersed in the water in a tepid state, about a quarter of an hour, twice a day.

When sea-water poultices bring out pimples, in cases of scrophulous ulcers on the legs and feet, Sir E. Home informs us, that this disagreeable circumstance may be obviated by diluting such water with an equal quantity of a decoction of poppies. After a time, the salt water may be tried by itself again. While each fresh poultice is preparing, the part should also be immersed in such water warmed.

When there is a tendency to anasarca, or when there is an unusual coldness in the limb, unattended with any propensity to mortification, tepid salt-water may be used with infinite advantage.

4. *Ulcers, which may be cured by the Argentum Nitratum.*

Sir E. Home notices, under this head, an ulcer, which does not penetrate more deeply, than the cutis; but, spreads in all directions, producing ulceration on the surface of the skin, and often extending nearly through its whole thickness. The part, first affected, heals, while the skin beyond is in a state of ulceration.

Of this description are, a leprous eruption, mostly seen in men impressed in Ireland; a disease of the skin induced by buboes, which have continued a great while after the venereal virus has been destroyed; and the ring-worm.

All these diseases are most easily cured by applying to them a solution of the argentum nitratum.

The leprous eruption is communicated by contact, and makes its appearance in the form of a boil. This is converted into an ulcer, which discharges a fetid fluid, by which the surrounding skin is excoriated, and the ulceration is extended over a large surface. The pain is the most severe, and

the discharge greatest, in hot weather. The parts first diseased heal, while others are becoming ulcerated, and the disease is always rendered worse, by spirituous liquors, salt provisions, and catching cold.

Sir E. Home remarks, that the disease in the skin, produced by the effects of very irritable buboes, in constitutions broken down by mercury, is attended with ulceration of a more violent, deep, and painful kind, than the foregoing distemper. The progress of this disorder is, in other respects, very similar to that of the leprous eruption.

Although the ringworm only occurs in the form of an ulcer in warm climates, a mild species of the affection takes place in summer-time in this country. It seems to be infectious; though it often occurs without infection. It commences with an efflorescence, which is attended with very trivial swelling, and spreads from a central point. The circumference of the efflorescence becomes raised into a welt, while the rest assumes a scurfy appearance. The welt becomes covered with a scab, which falls off, and leaves an ulcerated ring, in general, not more than a quarter of an inch wide. The outer margin of this ring continues to ulcerate, while the inner one heals, so that the circle gets larger and larger. The discharge consists of a thin, acrid fluid, which seems to have a great share in making the disease spread.

For all the three preceding diseases, a solution of the argentum nitratum is strongly recommended by Sir E. Home.

5. *Ulcers, which yield to Arsenic.*

The sores, which are named *noli me tangere*, derive great benefit from this powerful remedy. Sir E. Home observes, that they are nearly allied to cancer, differing from it in not contaminating the neighbouring parts by absorption, and only spreading by immediate contact.

From some cases, which fell under Sir E. Home's observation, he discovered, that arsenic was not only efficacious as an external, but also as an internal remedy. I shall not unnecessarily enlarge upon this subject in the present place, as the reader may refer to the articles *Arsenic*, *Cancer*, and *Noli Me Tangere*, for additional information, relative to the uses of this potent mineral in the practice of surgery.

Sir E. Home is an advocate for its employment, both internally and externally, for ulcers of untoward appearance on the legs. The *fungated* ulcer is particularly pointed out by this gentleman as being benefited by arsenic. This ulcer occurs on the calf of the leg, and on the sole of the foot. From its surface, a fungus shoots out, which is entirely different from common granulations. The new formed substance is radiated in its structure, the

bottom of the ulcer being the central point, and the external surface, which is continually increasing, the circumference. The substance of this fungus is very tender, and readily bleeds. The first stage of the disease sometimes has the appearance of a scrophulous affection of the metatarsal bones; but, the parts seem more enlarged, and, when the skin ulcerates, a fungus shoots out, and betrays the nature of the case.

One species of the fungated ulcer is capable of contaminating the lymphatic glands; the other is not so. The first is represented by Sir E. Home as being incurable by arsenic, or any other known medicine.

The second yields to this remedy. Sir E. Home uses a saturated solution, made by boiling white arsenic in water, for several hours, in a sand heat. He gives from three to ten drops internally; and, for outward use, dilutes a dram with two pints of water, making it afterwards gradually stronger and stronger, till it is of double strength. The application may either be made in the form of a poultice, or by dipping lint in the lotion.

The best and safest preparation of arsenic, both for internal and external use, is the kali arsenicatum. The mode of employing it may be learnt by turning to the articles *Arsenic*, *Aqua Kali Arsenicati*, *Noli Me Tangere*, &c.

6. Ulcers attended with Varicose Veins.

A certain kind of ulcer is very apt to occur on the inside of the leg, and is equally difficult to cure, and liable to break out again. It has the look of a mild, indolent sore; but, the branches and trunk of the vena saphena are enlarged, and this varix of the veins keeps the ulcer from healing. The sore is seldom deep, usually spreads along the surface, and has an oval shape, the ends of which are vertically situated. There is a pain affecting the limb rather deeply, extending up in the course of the veins, and exasperated by keeping the leg a long while in an erect posture.

This is a kind of ulcer, which derives immense benefit from a tight roller, applied from the toes to the knee, although the direct operation of the pressure of the bandage on the sore is itself productive of no particular good.

Sir E. Home found, however, that many patients could not bear to wear laced stockings, or tight bandages, and that others received no relief from them. Hence, this gentleman was led to consider what else could be done for the cure of the varicose state of the veins. He represents, that, in consequence of the size of the vena saphena, and its numberless convolutions, the return of blood from the smaller branches is so impeded, as to retard the

circulation in the smaller arteries, and to interfere with their action in forming healthy granulations. The coats, and valves of the veins also become thickened, so that the latter parts (the valves) do not do their office of supporting the weight of the column of blood.

These reflections induced Sir E. Home to think, that some benefit might be obtained by taking off a part of the pressure of this column of blood, by making a ligature round the vena saphena, where this vessel passes over the knee-joint. Thus the cavity of the vein at this part would be obliterated, and a kind of artificial valve would be formed.

This gentleman recommends the following way of performing the operation: "As the veins are only turgid in the erect posture, the operation should be performed while the patient is standing; and if placed upon a table, on which there is a chair, the back of the chair will serve him to rest upon; and he will have the knee-joint at a very convenient height for the surgeon. The leg to be operated upon must stand with the inner ankle facing the light, which will expose very advantageously the enlarged vena saphena passing over the knee-joint. While the patient is in this posture, if a fold of the skin, which is very loose at this part, is pinched up transversely, and kept in that position by the finger and thumb of the surgeon, on one side, and of an assistant on the other, this fold may be divided by a pointed scalpel, pushed through with the back of the knife towards the limb to prevent the vein being wounded; much in the same way, as the skin is divided in making an issue. This will expose the vein sufficiently; but, there is commonly a thin membranous fascia confining it in its situation; and, when that is met with, the vein had better be laterally disengaged by the point of the knife. This is most expeditiously done by laying hold of the fascia with a pair of dissecting forceps, and dividing it; for it is difficult to cut upon parts, which give little resistance, and there is a risk of wounding the vein. After this a silver crooked needle, with the point rounded off, will readily force its way through the cellular membrane connected with the vein, without any danger of wounding the vessel, and carry a ligature round it. This part, or, indeed, what may be considered as the whole of the operation, being finished, the patient had better be put to bed, so as to allow the vein to be in its easiest state, before the ligature is tied, and then a knot is to be made upon the vein: this gives some pain; but, it is by no means severe. The edges of the wound in the skin are now to be brought

together by sticking plaster, except where the ligature passes out, and a compress and bandage applied, so as to keep up a moderate degree of pressure on the veins, both above and below the part included in the ligature." (*Home on Ulcers*, p. 296. edit. 2.)

It appears that A. Paré proposed and performed an operation, similar to that described by Sir E. Home. (See *A. Paré's Works*, translated by Johnson; folio edition, Page 319.) An account of Mr. Brodie's operation for the cure of varicose veins, and some additional remarks on the treatment of ulcers accompanied with varices, will be found in a subsequent article. See *Varicose Veins*. A description of, what has sometimes been called the *hospital sore*, is given under the head of *Hospital Gangrene*.

S. 1801, edit. 2.; *Principles of Surgery*, by John Bell, Vol. 1. 1801; *Hunter on the Blood, Inflammation, &c.* *Brodie's Observations on the Treatment of Varicose Veins of the Legs*, in *Medico-Chirurgical Trans.* Vol. 7, P. 195, &c. *Richerand, Nosographie Chirurgicale*, Tom. 1, p. 121, &c. Edit. 4. *Boyer, Traité des Maladies Chir.* Tom. 2, p. 365, &c. Paris, 1814. *Roux, Voyage fait à Londres en 1814, ou Parallèle de la Chirurgie Angloise avec la Chirurgie Française*, p. 142, &c. Paris, 1815. *Dr. John Thomson's Lectures on Inflammation*, p. 423, &c. Edinb. 1813. *Dr. Dewar on the Treatment of Sinuous Ulcers*, in *Medico-Chirurgical Trans.* Vol. 7, p. 482, &c. The stages of several cutaneous affections, attended with ulceration, have been excellently described by *Dr. Bateman* in his valuable *Synopsis of Cutaneous Diseases*.

UNGUENTUM ACIDI SULPHURICI.—℞. Acidi Sulphurici 3j. Adipis Suillæ præparatæ 3j.—These are to be well mixed together in a glass mortar.

This ointment is said to have been used by *Dr. Duncan*, of Edinburgh, for curing the itch. It has the character also of being efficacious in the reduction of some chronic swellings of the joints. *Mr. Naylor*, of Gloucester, has employed frictions with this ointment, containing a good deal of camphor, for the purpose of reducing the swelling of the thyroid gland, in cases of bronchocle.

As the sulphuric acid is particularly destructive of vegetable substances, the parts, to which this ointment is applied,

should always be covered with flannel, instead of linen.

UNGUENTUM CANTHARIDIS vel *Lyttæ*.—℞. Cantharid. Pulv. ʒij. Aquæ Distillatæ ʒviij. Unguenti Resinæ Flavæ ʒviij. Boil the water with the cantharides, till one half of the fluid has evaporated. Then strain the rest, to which add the ointment of yellow resin. Evaporate the mixture in a water bath, saturated with sea-salt, until it is of the consistence of an ointment.

UNGUENTUM CETACEI.—℞. Cetaei 3vj. Cerae Albæ 3ij. Olivæ Olei. fluid uncias tres. These are to be melted upon a slow fire, and then briskly stirred till cold.—This ointment, spread on lint, serves as a simple dressing for wounds, ulcers, &c.

UNGUENTUM CERÆ CUM ACETO.—℞. Cerae Albæ ʒiv. Olei Olivæ ℥j. Aceti Distillati ʒij. The vinegar is to be gradually mixed with the two first ingredients, after these have been melted together. *Dr. Cheston* recommends this ointment for superficial excoriations, cutaneous eruptions, &c.

UNGUENTUM CONII.—℞. Foliorum Conii recentium. Adipis Suillæ præparatæ, sing. ʒiv. The hemlock is to be bruised in a marble mortar, after which, the lard is to be added, and the two ingredients thoroughly incorporated by beating. They are then to be gently melted over the fire, and after being strained through a cloth, and the fibrous part of the hemlock well pressed, the ointment is to be stirred till quite cold. To cancerous or scrophulous sores, this ointment may be applied with a prospect of advantage. (*Pharm. Chirurg.*)

The Pharmacopœia of *St. Bartholomew's Hospital* directs the unguentum conii, vel cicutæ, to be made as follows:—℞. Foliorum Cicutæ ℥j. Adipis Suillæ ℥iiss. Boil the leaves in the melted hog's-lard, until they become crisp. Then strain the ointment.

An hemlock ointment might be more conveniently made, by mixing the extractum conii with any common salve.

UNGUENTUM DIGITALIS.—℞. Foliorum Digitalis Purpureæ recentium. Adipis Suillæ præparatæ, sing. ʒiv. This ointment may be made in the same manner as the unguentum cicutæ, and tried in the same cases as the latter.

UNGUENTUM ELEMI COMPOSITUM.—℞. Elemi ℥j. Terebinthinæ ʒx. Sevi Ovilli præparati ℥ij. Olei Olivæ ʒij. Melt the elemi with the suet; remove them from the fire, and mix them immediately with the turpentine and oil. Then strain the mixture.—Sometimes employed for dressing ulcers, which stand in need of stimulating applications.

UNGUENTUM GALLÆ CAMPHORATUM.—℞. Gallarum Pulveris Subtilissimi ʒij. Camphoræ ʒss. Adipis Suillæ præparatæ ʒij. Misc.—This is a very good

application to piles, after their inflammatory state has been diminished by the lotio aq. litharg. acet. and leeches.

UNGUENTUM HELLEBORI ALBI.—℞. Hellebori Albi Pulv. ℥j. Adipis Suillæ præparatæ ℥iv. Olei Limonis ℥ss. Misce.—This ointment will cure the itch, and several other cutaneous diseases. Tinea capitis will sometimes yield to it.

UNGUENTUM HYDRARGYRI FORTIUS.—℞. Hydrargyri purificati ℥ij. Adipis Suillæ præparatæ ℥xxij. Sevi Ovilli præparati ℥j. First rub the quicksilver with the suet, and a little of the hog's-lard, until the globules disappear; then add the remainder of the lard, and make an ointment.—This is the common, strong, mercurial ointment. Of its uses we need say nothing in this place.

UNGUENTUM HYDRARGYRI CAMPHORATUM.—℞. Unguenti Hydrargyri ℥j. Camphoræ ℥ss. Misce.—This is often recommended to be rubbed on thickened, indurated parts, with a view of exciting the action of the absorbents. Rubbed along the course of the urethra, it is very serviceable in diminishing and removing chordee.

UNGUENTUM HYDRARGYRI MITIUS.—℞. Unguenti Hydrargyri fort. ℥ij. Adipis Suillæ præparatæ ℥ij. Misce.—The weaker mercurial ointment is often rubbed on indurated, thickened parts and tumours, when the object is merely to promote their absorption; and, it is not advisable to employ the unguentum hydrargyri fort. lest a salivation should be induced.

UNGUENTUM HYDRARGYRI NITRATIS.—℞. Hydrarg. Purificati ℥j. Acidi Nitrosi ℥ij. Adipis præparatæ ℥vj. Olei Olivæ ℥iv. Dissolve the quicksilver in the nitrous acid; and whilst the solution is yet hot, mix with it the oil and hog's-lard, previously melted, but beginning to concrete, by being exposed to the air. This ointment is a celebrated application to the inside of the eyelids, in cases of chronic ophthalmia, and also to specks on the cornea. When blended with a little olive oil, it also forms a very eligible stimulating dressing for numerous kinds of sores. It is particularly efficacious in curing tinea capitis, and many other herpetic and cutaneous diseases.

UNGUENTUM HYDRARGYRI NITRICO-OXYDI.—℞. Hydrargyri nitrico-oxydi ℥j. Cerae Albæ ℥ij. Adipis præpar. ℥vj. Misce.—This is a most common application to indolent ulcers, and sores in general, which require being stimulated.

UNGUENTUM HYDRARGYRI PRÆCIPITATIALBI.—℞. Hydrarg. Præcip. Albi ℥j. Adipis præparatæ ℥iss. Misce. An useful application in certain cases of porrigo, and some other cutaneous diseases.
See Tinea.

UNGUENTUM LIQ. PLUMBI ACETATIS.—℞. Liquoris Plumbi Acetatis ℥v. Adipis Suillæ ℥ij. Cerae Albæ ℥iv. Melt the ingredients together, and continue to stir them till cold.—This is an excellent saturnine ointment for ulcers with inflamed edges, and it may be employed with great advantage as a simple dressing in numerous instances.

UNGUENTUM OPHTHALMICUM.—℞. Adipis Suillæ præparatæ ℥ss. Tutia præparatæ, Bol. Armen. sing. ℥ij. Præcip. Hydrarg. Albi ℥j. Misce.—This is Janin's celebrated ophthalmic ointment, which may be used for the same diseases of the eye and eye-lids, as the unguentum hydrargyri nitrati. It must be at first weakened with about twice its quantity of hog's-lard.

UNGUENTUM PICIS.—℞. Picis, Sevi Ovilli præparati, sing. ℥ss. Melt, and then strain them.

UNGUENTUM PICIS COMPOSITUM.—℞. Unguenti Picis, Unguenti Cerussæ Acetatæ, sing. ℥ss. Misce.

The two preceding ointments are applicable to cases of tinea capitis, and some eruptive complaints. Also to some kinds of irritable ulcers.

UNGUENTUM PICIS CUM SULPHURE.—℞. Unguenti Picis, Unguenti Sulphuris, sing. ℥iv. Misce.—This is one of the most common, and, I believe, the most efficacious, applications for curing tinea capitis, or porrigo.

UNGUENTUM PLUMBI SUPERCETATIS.—℞. Plumbi Superacetatis ℥ij. Cerae Albæ ℥ij. Olei ℥ss. The superacetate of lead, previously powdered, is to be triturated with part of the olive oil. The melted wax and rest of the oil are then to be added. This ointment is a good dressing for cases requiring a mildly astringent, antiphlogistic application.

UNGUENTUM RESINÆ FLAVÆ.—℞. Resinæ Flavæ, Cerae Flavæ sing. ℥ij. Olei Olivæ ℥ij. Melt the resin and wax with a slow fire; then add the oil, and strain the mixture while hot.—This is a common application to ulcers, which stand in need of being gently stimulated.

UNGUENTUM SAMBUCCI.—℞. Florum Sambuci, Adipis Suillæ, singulorum ℥ij. The hogs-lard being melted, boil the elder-flowers in it till they become crisp, then strain the mixture.

UNGUENTUM SULPHURIS.—℞. Adipis Suillæ ℥ss. Florum Sulphuris ℥iv. Misce.

UNGUENTUM TUTIÆ.—℞. Tutia præparatæ, Unguenti Spermatæ Ceti, q. s. Misce.—Used for smearing the borders and inside of the eyelids, in cases of chronic ophthalmia, &c.

UNGUENTUM TUTIÆ COMPOSITUM.—℞. Tutia præparatæ, Lapidis

Calaminaris præparati, sing. ʒvj. Camphoræ ʒij. Unguenti Sambuci ℥j. Misce.

This formula is contained in the Pharmacopœia of St. Bartholomew's Hospital. It may be applied, in some cases, to the inside of the eyelids, also to piles; certain ulcerations, excoriations, &c.

UNGUENTUM ZINCI.—℞. Zinci oxydi ʒj. Adipis præpar. ʒvj. Misce.—Sometimes used in the same affections of the eye and eye-lids, in which the unguentum hydrargyri nitrati, and the unguentum ophthalmicum, are employed.

UNGUIS. (*A Nail*.) Some surgical authors have applied this term to a collection of pus, or matter in the eye, when the abscess has appeared, through the cornea, to be shaped like a finger nail.

UNGULA. (*A Hoof*.) A collection of matter in the eye, shaped like a hoof.

UNION BY THE FIRST INTENTION.—When the opposite surfaces of a wound are brought into contact, and grow together at once, without suppurating, union by the first intention is said to have taken place. When wounds heal by suppurating, granulating, &c. they are sometimes surgically described as getting well by the second intention. See *Wounds*.

URETHRA, STRICTURES OF.—It has been noticed by Mr. John Hunter, that most obstructions to the passage of the urine, if not all, are attended with nearly the same symptoms. Few persons take notice of the first symptoms of a stricture, till they have either become violent, or other inconveniencies have been the consequence. A patient may have a considerable stricture, and yet be unconscious, that his urine does not freely come away; he may often have, in consequence of a stricture, a tendency to inflammation and suppuration in the perinæum, without feeling any obstruction to the passage of his urine, or suspecting that he has any other complaint.

There are three kinds of strictures; viz. the true permanent one, which arises from an alteration in the structure of a part of the urethra; the mixed case, consisting of a permanent stricture and a spasm; and, thirdly, the true spasmodic stricture.

In all these obstructions, Mr. Hunter remarks, that the stream of water becomes small in proportion to the stoppage; but, though this symptom is probably the first, it is not always observed by the patient. In some instances, the water is voided only by drops, and then it cannot escape notice. In other cases, the stream of urine is forked, or scattered. Under such circumstances, Mr. Hunter recommends the passage to be examined with a bougie; and, if one of a common size can be readily introduced, the difficulty of voiding the

urine is likely to depend on a diseased enlargement of the prostate gland, which should, therefore, be examined. See *Prostate Gland*.

The spasmodic stricture may be known by its being only of temporary duration. This kind of case, and more particularly the permanent stricture, are generally attended with a gleet. The latter complaint is often for a long while suspected as being the only one, and the surgeon finds all his efforts, to effect a cure, fruitless.

In diseases of the urethra, and also of the prostate gland and bladder, there is commonly an uneasiness about the perinæum, anus, and lower part of the abdomen. (*Hunter*.)

The first progress of the contraction is, in general, very slow; but, when once it has so far increased, that the urethra is not wholly relaxed by the force of the urine, its subsequent advances are more rapid, and new symptoms are perceived. The urine is voided more frequently, does not pass without a considerable effort, attended with pain, and a straining sensation continues, after the bladder is emptied. If the patient accidentally catches cold, drinks a glass of spirituous liquor, acid beverage, or punch, commits an excess in drinking wine, or removes quickly from a warm to a cold temperature, the urine will, perhaps, pass only in drops, or be entirely obstructed. These causes induce, in the contracted part, a spasmodic action, by which it is closed. Cold, externally applied to the body, has so great an effect upon a spasmodic stricture, that a patient, who can make water without the smallest difficulty in a warm room, is often quite unable to void a drop, on making the attempt in the open air. However, on returning to a warm room, and sitting down a little while, he becomes able again to expel his urine. The symptoms of a stricture are more frequent in persons, who lead a sedentary life, than in others whose pursuits are more active. (*Home*.)

Strictures in the urethra, being attended with a discharge and pain in making water, especially after any excess, are frequently regarded and treated as a gonorrhœa. These two symptoms often come on a few hours after connexions with women; the degree of inflammation is very slight; the discharge is the first symptom, and is more violent at the commencement, than at any other period. The inflammation subsides in a few days, leaving only the discharge, which also frequently disappears in five or six days, whether any means are employed or not, for its removal. (*Home*.)

What renders a stricture particularly apt to be mistaken for a gonorrhœa, is the circumstance that, in both diseases, the

pain in making water is experienced about an inch and a half from the orifice of the glans penis.

In a more advanced stage, the strictured part of the urethra is always much narrower, than the rest of the canal. However, it retains the power of becoming contracted and relaxed. In the contracted state, the passage is closed up; in the relaxed, the urine can pass through it in a small stream.

The spasmodic contraction must act with considerable force, since the urine cannot even pass in a small stream, and a small bougie, which, in a relaxed state of the urethra, met with no resistance, can now be scarcely introduced at all. Also, if the bougie be allowed to remain for a few minutes in the stricture, it is not unfrequently grasped so tightly by the spasmodic contraction, that, when an attempt is made to withdraw it, some force is requisite to succeed. The bougie, when examined, seems as if it had had an impression made round it by a piece of packthread. (*Home.*)

In old cases of stricture, the muscular coat of the bladder becomes thickened and stronger, than natural, in consequence of more force being necessary to propel the urine through the obstructed part. The bladder, in this thickened state, does not admit of the usual dilation, so that the patient is obliged to make water very frequently, and he is unable to pass the whole night without making this evacuation once or twice. (*Home.*)

A nocturnal emission of the semen is another very common symptom of a stricture; and some patients seem to have no other complaint attendant on the affection of the urethra.

A periodical discharge is sometimes brought on by cold, or other occasional causes. The inflammation extends to the bladder; the frequency of making water is considerably increased, and the urine very turbid. It is voided for twelve, or twenty-four hours, once or even twice every hour; and, when allowed to stand, it deposits a substance in the form of powder, consisting of coagulable lymph. This is the slightest kind of attack.

Sometimes the bladder is inflamed in a greater degree, and secretes pus, which is discharged with the urine. In a still more violent attack, the discharge is similar to the white of an egg, and particularly adhesive. Sir Everard Home states, that it has been discovered by examinations after death, to be the vitiated secretion of the prostate gland. When the inflammation of the bladder becomes still worse, the affection sometimes extends to the peritoneum, and the patient dies.

Since strictures of long standing always impede the passage of the urine, the blad-

der acts with augmented force to overcome the resistance. In this manner, the stricture is kept in a continual state of irritation, and made to contract in a greater degree.

In a few cases, indeed, the diseased part of the urethra is rendered quite impervious; and the patient's life is preserved by the urethra ulcerating, at some point within the obstruction, and fistulous openings taking place in the perinæum. See *Fistula in Perinæo*.

Strictures are frequently attended with constitutional symptoms, one of the most common of which, in warm climates, is a complete paroxysm of fever. The cold fit is very severe; this is followed by a hot fit, and then a very profuse perspiration. During the rigor, nausea and vomiting generally occur, and at this period the patient has occasion to make water frequently, seldom experiencing at the same time any strangury. When the fit is tolerably complete, the patient suffers, in general, only one; in the opposite circumstance, two; but, a greater number rarely happen. Such febrile paroxysms are not frequent in cold countries; but do every now and then take place, particularly in consequence of exposure to cold, excesses, and the introduction both of common and armed bougies.

With regard to the formation of strictures, Sir Everard Home has noticed, that the membrane of the urethra, like every other muscular structure, is liable to a spasmodic contraction, in which state the canal loses the power of relaxing itself again, till the spasm is removed. This spasmodic stricture is only a wrong action of the urethra; and, if the parts could be examined in their relaxed state, there would be no appearance of disease.

A part of the urethra, once disposed to become preternaturally contracted, generally becomes more and more affected in this manner, and, at last, becomes permanently narrower. The case now becomes both a permanent stricture and a spasmodic one; being so far permanent, that it is always narrower, than the rest of the canal, and so far spasmodic, that it may become contracted in a still greater degree.

When the contraction is not considerable, it appears, on examination after death, to be merely a narrowing of the urethra; but a permanent stricture, in a more advanced state, usually consists of a ridge, which forms a projection in the passage. (*Home.*)

Mr. Hunter informs us, that the disease generally occupies no great length of the passage; at least, that this was the case in most of the instances, which he had examined. In these the contraction was not

broad, than if it had been produced by surrounding the urethra with a piece of packthread; and in many it had a good deal of the appearance, which one may fancy such a cause would produce. Mr. Hunter states, however, that he had seen the urethra contracted for above an inch in length, owing to its coats, or internal membrane, being irregularly thickened, and forming a winding canal.

A stricture does not always arise from an equal contraction of the urethra all round; for, in some instances, the contraction is only on one side. This contraction of one side of the canal only throws the passage to the opposite side, which often renders the introduction of a bougie difficult. The contracted part is whiter, than the rest of the urethra, and is harder in its consistence. In some few cases, there are more strictures than one. Mr. Hunter mentions his having seen half a dozen in one urethra, and he observes, that a stricture is frequently attended with small tightnesses in other parts of the urethra.

Mr. Hunter remarks, that every part of the urethra is not equally subject to strictures, the bulbous portion being much the most subject to the disease. A stricture is sometimes situated on this side of the bulb, but very seldom beyond it, that is, nearer the bladder. Mr. Hunter never saw a stricture in that part of the urethra, which passes through the prostate gland; and the bulb, besides being the most frequent seat of this disease, is also subject to it in its worst forms. (*Hunter.*)

Sir E. Home has measured the length of the urethra in different subjects, and examined the diameters of the several parts of the passage. Strictures, according to this gentleman, occur most commonly just behind the bulb of the urethra, the distance from the external orifice being $6\frac{1}{2}$, or 7 inches. The situation, next in the order of frequency, is about $4\frac{1}{2}$ inches from the orifice of the glans. The disease does also occur at $3\frac{1}{2}$ inches, and, sometimes, almost close to the external orifice. The two parts of the urethra, most frequently affected with strictures, are naturally the narrowest. Sometimes the very orifice of the urethra is contracted, and the circumstance often leads to an erroneous supposition, that the whole canal is naturally formed of the same size. The prepuce also is observed to be particularly often affected with a natural phimosis, in persons, who have strictures in the urethra.

In almost all the cases, which Sir E. Home has met with, there has been one stricture, about seven inches from the external orifice, whether there were any others, or not.

With respect to the causes of strictures, some writers have imputed the disorder to the effects of the venereal disease, and

often to the method of cure. Mr. Hunter, however, entertained very strong doubts, whether strictures commonly, or even ever, proceeded from these causes; though he acknowledges, that since most men have had venereal complaints, a refutation of the above opinion is very difficult. Mr. Hunter was led to think, that strictures did not commonly arise from venereal causes, from reflecting that strictures are common to most passages in the human body. They often take place in the œsophagus; the intestines, particularly, the rectum; the anus; the prepuce, so as to produce phimosis; and in the lachrymal duct, so as to occasion a fistula lachrymalis. Strictures sometimes take place, when there have been no previous venereal complaints. Mr. Hunter mentions his having seen an instance of this kind in a young man, nineteen years of age, who had had the complaint for eight years, and which therefore began, when he was only eleven years old. He was of a weak, scrophulous habit. Mr. Hunter had also seen a stricture in a boy only four years old, and a fistula in perinæo in consequence of it. Strictures happen as frequently in persons, who have had the gonorrhœa in a slight degree, as in others, who have had it in a severe form.

Many believe, that strictures arise from the use of injections in the treatment of the gonorrhœa; but, Mr. Hunter thought, that this opinion was founded on prejudice, and he states, that he had seen as many strictures after gonorrhœas, which had been cured without injections, as after those, which had been treated with these latter applications.

Mr. Hunter also disbelieved the idea, that strictures are a consequence of ulcers in the urethra; for, ulcers hardly ever occur in this passage, except when there are strictures. It is now generally admitted, that, in gonorrhœa, no sores exist in the urethra.

TREATMENT OF STRICTURES, WITH COMMON BOUGIES, ON THE PRINCIPLE OF DILATATION.

Mr. Hunter remarks, that the cure of strictures may be accomplished, either by a dilatation of the contracted part, or a destruction of it by ulceration, or escharotics. The dilatation is accomplished by means of bougies; but, Mr. Hunter considered, that a cure, thus effected, was seldom or never more, than temporary. The removal of the stricture by ulceration, may also be effected with bougies. Its destruction with caustic used formerly to be executed through a cannula, contrived for the purpose; but, is now performed by means of caustic, or armed bougies.

The cure by dilatation is principally me-

chanical, when effected by bougies, the powers of which are generally those of a wedge. However, Mr. Hunter remarks, that their ultimate effect is not always so simple as that of a wedge upon inanimate matter; for, pressure makes living parts either adapt themselves to their new position, or else recede by ulceration. Bougies, of course, either dilate strictures, or make them ulcerate.

The disease has generally made considerable progress, before the patient seeks surgical assistance, and the stricture may be so advanced, that a small bougie cannot be made to pass, without a great deal of trouble. If the end of a small bougie, let it be ever so small, can be introduced through the stricture, the cure is then in our power. However, a small bougie frequently cannot be passed in the first instance, and even not after repeated trials.

Often, when the stricture is very considerable, a great deal of trouble is given by occasional spasms, which either resist the introduction of a bougie altogether, or only allow a very small one to pass. At other periods, however, a larger one may be introduced. In these circumstances, Mr. Hunter mentions, that he was sometimes able to get the point of a bougie to enter, by rubbing the outside of the perinæum with the finger of one hand, while he pushed the bougie on with the other. The same eminent practitioner often succeeded by letting the bougie remain a little while close to the stricture, and then pushing it on. Sometimes, the spasm may also be taken off by dipping the glans penis in cold water.

Although, in cases of permanent strictures, the bougie may not pass at first, yet, after repeated trials, it will every now and then find its way. In this manner, future attempts become more certain and easy.

However, the success of the subsequent trials to introduce a bougie does not always depend on the instrument having been once, or twice passed. Sometimes, it can be introduced to-day; but, not to-morrow; and, in this state, the case may continue for weeks, notwithstanding every trial we can make. Mr. Hunter observes, however, that, in general, the introduction of the bougie becomes gradually less difficult, and, therefore, that we ought not to despair of success in any case.

When the passage is very small, it is not easy to know, whether the bougie has entered the stricture, or not: for bougies, as slender as those, which must be at first employed, bend so very easily, that the surgeon is apt to fancy, that they are passing along the urethra, while they are only bending. Mr. Hunter advises the surgeon to make himself, at first, acquainted with the situation of the stricture, by means of

a common-sized bougie. Then he is to take a smaller one, and when its point arrives at the stricture, the instrument is to be gently pushed forward; but, only for a short time. If the bougie has passed further into the penis, the surgeon may know how far it has entered the stricture by taking the pressure off the bougie. For, if it recoil, he may be sure, that it *has not passed*; at least, has not passed far; but, only bent. On the contrary, if it remain fixed, and do not recoil, it has certainly entered the stricture.

Mr. Hunter informs us, however, that the preceding remarks are not so applicable, when a very small bougie is employed, which may become bent, without our being aware of the circumstance.

A bougie may frequently be introduced a very little way, for instance, only one-tenth of an inch, and then it bends, and cannot be pushed further. To determine whether this is the case, Mr. Hunter says, it is necessary to withdraw the bougie and examine its end. If the end be blunted, we may be sure that the bougie has not entered at all; but, if it be flattened, for an eighth, or tenth, of an inch, be grooved, or have its outer waxen coat pushed up to that extent; or, if there be a circular impression made upon the bougie, or only a dent on one side, made by the stricture; we may be sure, that the instrument has passed as far as these appearances extend. It then becomes necessary to introduce another of exactly the same size, and in the same manner, and to let it remain as long as the patient can bear it, or convenience will allow. By repetitions of this plan, the stricture will be overcome.

Mr. Hunter remarks, that the time, which each bougie ought to remain in the passage, must be determined by the feelings of the patient; for, if possible, no pain should ever be given. If the patient should experience very acute pain when the bougie is passing, it ought not to be left in the urethra above five, or, at most, ten minutes; or, not so long, if the pain be exceedingly severe. Each time of application should afterwards be lengthened so gradually as to be imperceptible to the feelings of the patient, and the irritability of the parts. Mr. Hunter affirms, that, he has known many patients, who could not bear a bougie to remain in the passage ten, or even five minutes, till after several days, and even weeks, but, who in time were able to wear the instrument for hours, and this, at last, without any difficulty. The best time for keeping a bougie in the urethra, is when the patient has least to do; or, in the morning, while he is in bed, if he can introduce the instrument himself.

Mr. Hunter next observes, that the bougie should be increased in size, according to the facility, with which the stricture

becomes dilated, and the ease, with which the patient bears the dilatation. If the parts are very firm, or very irritable, the increase of the size of the bougie should be very slow, so as to allow them to become gradually adapted to the augmented size of the instrument. But, if the sensibility of the parts will allow, the increase of the size of the bougie may be somewhat quicker, but, never more sudden, than the patient can easily bear. The surgeon must continue to increase the size of the bougie, till one of the largest size can freely pass; nor should the use of this be discontinued till after three weeks, or a month, in order that the dilated part may have time to become habituated to its new position, and lose its disposition to contract again. However, Mr. Hunter believed, that the permanency of a cure, effected on the principle of dilatation, could seldom be depended upon.

CURE OF STRICTURES BY ULCERATION.

This is also accomplished by means of a bougie, and the plan may be tried both when the instrument can, or cannot, be introduced through the stricture. In the first instance the method is less proper; because the stricture admits of being dilated.

In order to cure a stricture by making it ulcerate, the bougie is to be introduced as far through the contracted part as possible, and the size of the instrument is to be augmented, as fast as the sensations of the patient can well bear. In this manner, ulceration will be produced in the part, which is pressed, and, Mr. Hunter remarks, that the cure will be more lasting, because more of the stricture is destroyed, than when the parts are simply dilated. This eminent surgeon notices, however, that few patients will submit to this practice, and that few, indeed, would be able to bear it, since it is apt to bring on violent spasms in the part, attended with a very troublesome retention of urine.

If the smallest bougie cannot be made to pass a stricture, by using some degree of force, dilatation becomes impracticable; and, as the stricture must be destroyed, something else must be tried. In many cases, says Mr. Hunter, it may be proper to get rid of the stricture by making it ulcerate, or, in other words, be absorbed. Bougies, intended to excite ulceration, need not be so small, as in the foregoing cases, as they are not designed to be passed through the stricture; and, in consequence of being of the common size, they may be more surely applied to the parts, causing the obstruction. The force, applied to a bougie, in this case, should not be great; for, a stricture is the hardest part of the urethra; and if a bougie is forcibly pushed

on, its end may slip off the stricture, before ulceration has commenced, and make a false passage for itself in the corpus spongiosum urethræ.

In trying to cure strictures by ulceration, the utmost attention must be paid; and, if the patient does not make water better, notwithstanding the bougie passes further, the surgeon may be sure, that he is forcing a false passage.

When the stricture has so far yielded, as to allow a small bougie to be introduced, the treatment is then to be conducted on the principle of dilatation.

Mr. Hunter observes, that whenever a bougie of a tolerable size passes with ease, and the parts and the patient have become accustomed to it, the surgeon need no longer attend for the purpose of introducing it. The patient may now be allowed to introduce bougies himself; and when he can do this with ease, the business may be trusted to him, as he can make use of the instruments at the most convenient times, so that they may be more frequently, and longer, applied. In the mean while, the surgeon should only pay occasional visits. Mr. Hunter adds, that, this practice of the patient, under the surgeon's eye, by which means, the former learns the art of introducing bougies, is the more necessary, since strictures are diseases, which commonly recur; and, therefore, no man, who has ever had a stricture, and is cured of it, should rely on the cure as lasting; but, should always be prepared for a return, and always have some bougies by him. He should not go a journey, even of a week, without them; and the number should be according to the time, which he is absent, and the place, to which he is going; for in many parts of the world, he cannot be supplied with them.

To prevent the inconvenience of a bougie slipping out, or the mischief of its gliding into the urethra, a soft cotton thread must be tied round that end of the bougie, which is out of the urethra, and then round the root of the glans. This last part of the thread should be very loose. The projecting portion of the bougie should also be bent down upon the penis, by which means, it is rendered less troublesome, and more secure. (See *Hunter on the Venereal Disease*.) When a considerable part of the bougie remains out of the urethra, surgeons usually clip a piece of it off.

In many examples, in which a stricture is accompanied with excessive irritability in the urethra, much pain, and a tendency to frequent retentions of urine, whenever a common bougie is employed, it becomes advisable to alter the plan of treatment, and use either flexible metallic, or elastic gum bougies. (See *Bougie*.) Desault commonly cured all strictures by the skilful em-

ployment of flexible gum catheters, which his patients were directed to wear a certain length of time every day. These last instruments produce less pain and irritation, than any kind of bougie, more especially when the wires are withdrawn; and were I to be myself afflicted with strictures, I should feel strongly disposed to attempt their removal by the use of elastic gum catheters, which are unquestionably the mildest and least painful means of cure. I lately saw a case, in which the flexible metallic bougie seemed to cause much less irritation, than any other kind of bougie, but, in general, those made of elastic gum give the least pain. Metallic bougies possess the advantage of retaining the exact curvature of the passage, better than others. Small catgut bougies are chiefly eligible, when the cure by dilatation is preferred, and the smallest bougies of other descriptions cannot be introduced through the stricture.

CURE OF STRICTURES BY THE ARGENTUM NITRATUM.

Wiseman makes mention of the plan of curing strictures in the urethra by means of caustic. He observes, that, when the obstruction is a caruncle, and you cannot pass it, you may well conclude it is callous: "in which case, you may pass a cannula into the urethra to that caruncle, and, whilst you hold it there steady, you may convey a grain of caustic into the cannula, and press the caustic to it; and, whilst you hold it there, you will perceive its operation, by the pressing forward of the cannula."

About the year 1752, Mr. Hunter attended a chimney-sweeper, who had a stricture. Not finding, that any benefit was derived from the use of common bougies, for a space of six months, Mr. Hunter, unaware of the above passage in Wiseman, conceived, that the stricture might be destroyed by escharotics, and the first attempt, which he made, was with red precipitate. He put some salve on the end of a bougie, and then dipped it in red precipitate. The bougie, in this state, was passed down to the stricture; but, Mr. Hunter found, that it brought on considerable inflammation all along the inside of the passage, as he thought, in consequence of the precipitate being rubbed off, while the bougie was passing to the stricture. Mr. Hunter then introduced a silver cannula down to the stricture, and again passed the bougie with precipitate through the tube. As the patient, however, did not make water any better, and the smallest bougie could not be introduced through the stricture, he suspected, that the precipitate had not sufficient power to destroy the obstruction. Mr. Hunter was, there-

fore, induced to fasten a small piece of the argentum nitratum on the end of a piece of wire with sealing-wax, and introduce the caustic through the cannula to the stricture. After having made the application three times, at intervals of two days, he found, that the man voided his urine much more freely, and, on applying the caustic a fourth time, the cannula went through the stricture. A bougie was introduced for a little while afterwards, till the man had completely recovered.

Having experienced such success in the foregoing example, Mr. Hunter was encouraged to apply his mind to the invention of some instrument, better suited to the purpose, than the above contrivance. He succeeded in devising an improved instrument, although he acknowledges, that it was not perfectly adapted to strictures in every situation in the urethra. He remarks, that the caustic should be prevented from hurling the unaffected part of the urethra by introducing the active substance, through a cannula, down to the stricture; and it should be capable of protruding a little beyond the end of the cannula, by which means it will only act upon the stricture. The caustic should be fixed in a small portercrayon, and it is necessary to have a piece of silver of the length of the cannula, with a ring at one end, and a button at the other, of the same diameter as the cannula. The button forms a kind of plug, which should project beyond the end of the cannula in the urethra, so as to make a rounded end; or, Mr. Hunter says, the portercrayon may be formed with this button at its other end. The cannula, with the button, is to be passed into the urethra, and when it reaches the stricture, the silver plug should be withdrawn, and the portercrayon with the caustic introduced in its place; or, if the plug and portercrayon are on the same instrument, then it is only necessary to withdraw the plug, and introduce the portercrayon with the caustic. The plug, besides giving a smooth rounded end to the cannula, answers another good purpose, by preventing the tube from being filled with the mucus of the urethra, when the instrument is passing inward, which mucus would be collected in the end of the cannula, dissolve the caustic too soon, and hinder its application to the stricture.

When the stricture was beyond the straight part of the urethra, Mr. Hunter owned, that it was difficult to apply caustic to the disease through a cannula.

A better mode of applying lunar caustic to strictures was afterwards devised by Hunter, and has since been extensively introduced into practice by Sir E. Home. This gentleman directs us to take a bougie of a size, that can be readily passed down to the stricture, and to insert a small piece

of lunar caustic into the end of it, letting the caustic be even with the surface, but surrounded every where laterally by the substance of the bougie. This should be done some little time before it is required to be used; for, the materials, of which the bougie is composed, become warm and soft by being handled in inserting the caustic; and, therefore, the hold, which the bougie has of the caustic, is rendered more secure after the wax has been allowed to cool and harden. The bougie thus prepared, is to be oiled and made ready for use; but, before passing it, a common bougie of the same size is to be introduced down to the stricture, in order to clear the canal, and to measure the exact distance of the stricture from the orifice of the urethra. This distance being marked upon the armed bougie, it is to be passed down to the stricture, as soon as the other is withdrawn. The caustic, in its passage, is scarcely allowed to come into contact with any part of the membrane, because the point of the bougie, of which the *argentum nitratum* forms the central part, always moves in the middle line of the canal; and, indeed, the quickness with which it is conveyed to the stricture, prevents any injury of the membrane lining the passage when the caustic accidentally touches it.

In this mode the caustic is passed down with little or no irritation to the lining of the urethra, it is applied in the most advantageous manner to the stricture, and can be retained in that situation sufficiently long to produce the desired effect.

The reasons urged in favour of the employment of bougies armed with the lunar caustic, are: that a permanent cure is effected, which common bougies cannot accomplish; that the pain, arising from the application of the *argentum nitratum* to the stricture, is very inconsiderable; and that neither pain nor inflammation are found to ensue. The meaning of these remarks, however, is to be received as a general one, liable to exceptions. Indeed, Sir E. Home himself has candidly acknowledged, that some inconveniences occasionally follow the use of armed bougies. But, what practice, however judicious and eligible, is altogether free from occasional ill-consequences? Sir E. Home remarks, that against treating strictures of the urethra, with caustic bougies, numerous objections have been adduced, and many bad consequences have been attributed to the practice without any real foundation; "for, whatever, *à priori*, might be supposed the effects of so violent an application, to a membrane so sensible and irritable, as the urethra, and I will admit, that it is very natural to conceive they would be very severe, the result of experience, the only thing to be relied on, evinces

the contrary. The pain, that is brought on, is by no means violent; and neither irritation, nor inflammation, is found to take place.

"That cases do occur, in which strictures have produced so much mischief, and rendered so great an extent of the canal diseased, that the use of the caustic has proved unsuccessful, is certainly true; and several of these cases have fallen within my own knowledge. But, when it is stated that none, even of these, were made worse by its use; that no bad consequences attend it; and that no other mode, at present known, is equally efficacious; any occasional want of success cannot be considered as an objection to this mode of practice.

"But if the apprehension of violent effects from the caustic, however ill-founded, cannot be removed, let the alternative be considered; namely, the only operation previously in use, where a stricture cannot be dilated by the bougie.

"In those cases we are obliged to have recourse to means certainly more severe and violent, laying open with a knife the diseased urethra, and passing through the divided parts a flexible gum catheter into the bladder. This I have done myself, and have frequently seen it performed by Mr. Hunter, and it always succeeded; neither bringing on so much inflammation as was expected, nor being attended with any symptoms of irritation.

"This practice has by other surgeons been carried still further; the portion of diseased urethra has been dissected out, and entirely removed; nor has so severe an operation always brought on untoward symptoms; and patients have recovered.

"If the membrane of the urethra, when diseased, is capable of suffering so much injury, without any consequent symptoms of irritation, it cannot be doubted that it will bear with impunity to be touched, in a very partial manner, several different times with lunar caustic."

Sir Everard afterwards proceeds: "having met with a number of facts, from which a general principle appears to be established, that the irritable state of a stricture is kept up, and even increased, by the use of the bougie, but lessened and entirely destroyed by the application of lunar caustic; I am desirous to communicate my observations upon these facts, and to recommend the use of the caustic, in many cases of irritable stricture, in preference to the bougie.

"As the use of the caustic, upon this principle, is, I believe, entirely new, and is contrary to every notion, that has been formed upon the subject, it will require something more, than general assertion, to gain even the attention of many

of my readers, still more their belief; I shall therefore detail the circumstances, as they occurred, by which I conceive the propriety of this practice to be established; and afterwards make some observations upon the principle on which it depends.

"My connection in practice with Mr. Hunter afforded me opportunities of attending to cases of stricture, in all their different stages; many of them brought on during a long residence in India, attended with great irritability, and exceedingly difficult of cure.

"One case of this kind admitted the passing of a small bougie; but, in the course of three years, very little was gained by a steady perseverance in the use of that instrument, either in dilating the canal, or palliating the symptoms of stricture; this made me look upon the bougie as less efficacious, than I had always been taught to believe it. I was willing, however, to consider this as an uncommon case, depending more on the peculiarities of the patient's constitution, than on the nature of the disease: but, I found, on a particular enquiry, that several other gentlemen, from India, were under circumstances nearly similar; the bougie only preventing the increase of the stricture, but being unable to dilate it beyond a certain size; and when it was left off, the stricture in less than two months returned to its former state of contraction.

"What plan ought to be followed in such cases, I was then unable to determine; but, that the bougie could not be depended on was evident. During this suspense, the following case came under my care.

"In August, 1794, a gentleman consulted me for some symptoms, which had been considered as indicating the presence of gonorrhœa; but, as they did not yield to the common treatment in the usual time, he was induced to take my advice respecting the nature of his complaint. In the necessary enquiry, to obtain a perfect history of the case, among other things it was stated, that, nineteen years before, there was a stricture, which became very troublesome, and that Mr. Hunter, by the desire of the patient, had applied the caustic, by which the stricture was removed, and never afterwards returned. He said that he was one of the first persons on whom the caustic had been used. From this account, I was naturally led to believe that the stricture had gradually returned, and was now increased, so much as to produce the present symptoms; a discharge being almost always a symptom of stricture, when it is much contracted; but, upon examining the canal, a bougie of full size passed on to the bladder without the smallest impediment. I therefore took up

the case as an inflammation in the urethra; and large doses of the balsam copaiva, given internally, effected a cure.

"The circumstance of a stricture having been removed nineteen years before, and not returning, made a strong impression on my mind; and made me desirous to ascertain, whether this practice could be employed in cases of stricture in general, and the cure produced by it, equally permanent. A short time afterwards, I had an opportunity of trying it in the following case.

"A captain, in the East India Company's service, in September, 1794, applied to me for assistance. His complaints were, great irritation in the urethra and bladder, constant desire to make water, and an inability to void it, except in very small quantities. These symptoms had been at first supposed to arise from gonorrhœa, afterwards rendered more severe by catching cold: but, not yielding to the usual remedies for gonorrhœa, they were investigated more minutely, and a stricture was discovered in the urethra. The mode of treatment was now changed, and the bougie employed; but its use aggravated all the symptoms, and brought on so great a degree of irritability in the bladder and urethra, that there was an alarm for the patient's life, which was the reason for applying for my assistance.

"Besides the local symptoms, this patient had those of quick pulse, white tongue, hot and dry skin, loss of appetite, and total want of sleep, with frequent attacks of spasm on the bladder and urethra. A very small flexible gum catheter was passed, and the water drawn off, in quantity about a pint, which gave him great relief; this was repeated morning and evening, to keep the bladder in as easy a state as possible; but, in other respects, he continued much the same.

"As the present symptoms were brought on by the use of the bougie, little good was to be expected from that instrument; and where the urethra had been so easily irritated, and was disposed to continue in that state, there was no prospect of the use of the bougie afterwards effecting a cure. These circumstances I explained to the patient; and mentioned in proof of my opinion, the case, in which so little had been effected in three years.

"I then proposed to him a trial of the caustic, with a view to deaden the edge of the stricture, as the only probable means of effecting a cure. The degree of irritation was already great; I was, however, led to believe, that the application of the caustic was not likely to increase it; since, by destroying the irritable part, it might lessen, and even remove, the spasmodic affection; but if, contrary to my expect-

ation, the irritation continued, we still should be able to draw off the water, as the slough formed by the caustic would prevent the edge of the stricture from acting and obstructing the instrument.

"The application of the caustic was, upon these grounds, determined on; and it was applied in the following manner.

"I passed a common bougie, nearly the size of the canal, down to the stricture, to ascertain its exact situation, and to make the canal of the urethra as open as possible. The distance was then marked, upon a bougie armed with caustic, of the same size, which was conveyed down as quickly as the nature of the operation would admit. It was retained upon the stricture, with a slight degree of pressure; at first there was no pain from the caustic, but a soreness from pressure; in less than a minute, a change was felt in the sensation of the part, it was at first a heat, succeeded by the burning pain peculiar to caustic; as soon as this was distinctly felt, the bougie and caustic were withdrawn, having remained in the urethra about a minute altogether. The soreness, he said, was entirely local, by no means severe, was unaccompanied by irritation along the canal, and he thought the uneasiness in the bladder diminished by it. He described the pain as resembling very exactly the first symptoms of gonorrhœa. This sensation lasted half an hour after withdrawing the bougie.

"The caustic was applied about one o'clock in the forenoon, and he passed the day more free from irritation than he had been since the beginning of the attack, which had lasted six days. In the evening, the water was drawn off, with more ease than the night before. He passed a tolerable night, and, the next day, continued free from irritation. On the third day, the caustic was again applied in the forenoon; the painful sensation was less than on the former application, lasted a shorter time, and in an hour after the armed bougie was withdrawn, he made water freely for the first time since the commencement of his indisposition. He said the irritation in the bladder was removed, and he felt very well, his appetite returned, he slept very well, and continued to void his urine with ease.

"In this state, nothing was done till the fifth day, leaving always a day between the applications of the caustic.

"On this day a common-sized bougie went readily into the bladder; it was immediately withdrawn, and the cure was considered as complete; no bougie was afterwards passed, lest it might bring back an irritation upon the passage. I met this gentleman twelve months afterwards, and he assured me, he had continued perfectly well, and I have since learned, that, in three years, there has been no return.

"From the result of this case, I was encouraged to hope that the caustic might be applied to strictures in the urethra with more confidence than I had hitherto believed, since it evidently did not bring on, or increase the general irritation, but, on the contrary, seemed to allay it."

The foregoing case, together with another one, which Sir E. Home has related, convinced this gentleman, that he had discovered an effectual mode of treating such strictures, as do not admit of being relieved by the common bougie. Hence, he adopted the use of armed bougies, as a general practice; but, he has not concealed the circumstances, under which the method has not proved successful. Sir Everard informs us that "In some constitutions, where the patients have resided long in warm climates, every time the caustic is applied to a stricture, a regular paroxysm of fever called by the patient an *ague*, takes place; and this has been so violent as to render it impossible to pursue this mode of practice. Of this I have met with two instances. I consider this disposition to fever as the effect of climate, and not of any natural peculiarity of constitution; for the brother of one of these patients laboured under the same disease, but as he had not been in warm climates, it was removed by the caustic without his experiencing such attacks."

In *gouty* constitutions, attacks of the gout have in two instances brought on spasmodic constrictions, after the stricture had been removed by caustic. This, however, cannot be called a failure of the caustic. It only shews, that gout can affect strictures, and re-produce them.

"In some patients, the strictures are so obdurate, that the use of the caustic is necessary to be continued for a longer time than the parts can bear its application, or even that of the bougie passing along the urethra; irritation therefore comes on and stops the progress of the cure, and when the same means are resorted to again, the same thing takes place. The cases of failure of this kind that I have met with, some of which may yet ultimately be cured, if the patients will take the necessary steps for that purpose, amount in all to six.

"In some patients, the stricture is readily removed by the caustic, but, in a few weeks, contracts again. The stricture being wholly spasmodic, the caustic, by taking off the spasm, is allowed to pass through, and cannot completely destroy the stricture. Of this kind, I have met with one instance, which I must consider as a failure, as I have hitherto been unable to get the better of it.

"In those cases, where the caustic gradually removes the stricture, and brings

the urethra to a size, that allows the patient to make water perfectly well, if there is any return, it is not to be attributed to the failure of the caustic, but to the want of proper management, either from the caustic being too small, or its use left off too soon; but, all such cases are, I believe, within the power of being cured by the caustic, if its use is recurred to when that is found necessary."

For the generality of strictures in the urethra, which certainly do not occupy more extent of the canal, than if caused by a piece of packthread being tied round it, the bougies, armed with the lunar caustic, should be preferred. But, there are instances, in which the urethra is diminished in diameter, for an inch or more: in these cases, I cannot help considering the employment of common bougies most advantageous, that is to say, when they can be introduced through the stricture, so as to cure it on the principle of dilatation.

We shall conclude this part of the subject of strictures, with inserting some of the general directions given by Sir E. Home how to arm the bougie, and apply the lunar caustic to strictures.

In arming a bougie, it will be difficult to get a piece of caustic of a proper shape and size for the purpose, unless it be cast in a small cylindrical mould. "In this state (says Sir Everard) it is to be procured from Mr. Savigny, and, if these pieces are thicker than the bougie can readily enclose, by putting them in water, the outside quickly dissolves, so as to diminish their size, as much as is required. The piece of caustic, so prepared, is to be cut into small portions, about a quarter of an inch in length, and an orifice being made in the end of a bougie, the caustic is to be inserted into it, and the bougie rolled, so as to be made perfectly smooth, taking care, that the sides of the caustic are every where covered, and only the end exposed.

"This (continues Sir Everard Home) was the mode, in which I armed bougies, when I first took up this practice; but, it happened, that, in two or three instances, the caustic was left in the urethra; that canal, when in a very irritable state, grasped the bougie, and pulled the caustic out; I was therefore led to consider how such an accident might be prevented, and applied to the makers of bougies for that purpose. Mr. Pass, the late beadle of the Surgeons' Company, who dealt in bougies, discovered a very ingenious and effectual mode of securing the caustic. In forming the bougie, a piece of wire, the size of the caustic, is rolled up along with it, passing into the substance for half an inch; when the bougie is nearly finished, the wire is withdrawn, and the caustic inserted in its place; after this, the bougie is rolled

again, so that the sides of the caustic become firmly cemented to the linen, by means of the composition of the bougie, and when cold, cannot be separated by any force. In this way bougies are now generally armed.

"After the bougie has been thus prepared, the distance of the stricture from the external orifice is to be measured, and the canal cleared by passing a common bougie, fully as large as that which is armed. The armed bougie, with the distance marked upon it, is then to be introduced, and applied to the stricture; when it is brought in contact with the obstruction, it is to be steadily retained there, with a moderate degree of pressure at first, and less as it is longer continued, since the bougie becomes soft by remaining in the urethra, and readily bends, if the pressure is too great. The time it is to remain depends a good deal upon the sensations of the patient, and the length of time the parts have been diseased; but on the first trial, it should be less than a minute, as it then commonly gives greater pain than on any subsequent application. The pain produced by the caustic is not felt so immediately as it would be natural to expect; the first sensation arises from the pressure of the bougie on the stricture; a little after, there is the feeling of heat in the parts; and lastly, that of pain.

"As soon as the caustic begins to act, the surgeon, who makes the application, is made sensible of it by the smaller arteries of the parts beating with unusual violence, which is very distinctly felt by the finger and thumb, that grasp the penis.

"The pain that is brought on by the caustic lasts for some time after it is withdrawn; but this period differs in almost every patient, being sometimes extended to half an hour, and sometimes only a few minutes.

"The kind of pain is heat and soreness, which is not severe, not being accompanied by the peculiar irritation, upon so many occasions experienced by patients who have strictures; an irritation that cannot be described, which is most insupportable, and is too often brought on by dilating strictures with the bougie. After the caustic has been withdrawn, it is desirable, that the patient should make water before he uses exercise, as the parts are commonly more tranquil after having done so; but sometimes no water will flow at the first effort. When that is the case, it should not be urged, as it is not of any material consequence. It happens not unfrequently, that at the first time of making water, some blood passes along with it. This is rather favourable; as, when the parts bleed, the stricture usually proves to be so far destroyed, that at

the next trial the bougie passes through it. Every other day appears in general to be as often as it is prudent to apply the caustic. I have, however, done it every day, in very obstinate cases, where the parts are less sensible, without any detriment.

"The bougie, which is passed down to prepare the way for the caustic, and measure the distance for the armed bougie, must be made of soft materials, that it may readily receive an impression from the part against which it is pressed, and its colour should be light, so as to admit of those impressions being more distinctly seen. With the assistance of such bougies, I am able to discover the size and shape of the orifice of the stricture; to ascertain with accuracy the progress of the caustic upon it; to see whether it is on one side of the canal, or equally all round; and to apply the caustic accordingly.

"When the soft bougie passes through the stricture, by leaving it in the canal a few minutes, it can be known whether the stricture is completely destroyed or only relaxed; in the last case, there is an impression on the side of the bougie.

"So necessary is the information, which is acquired in this way, to enable the surgeon to prosecute the cure of stricture by means of the caustic, that without it I should have been unable to pursue this mode of practice. I should have wanted a sufficient degree of confidence to carry me on, which nothing but an accurate knowledge of what had been already done could have given, and, in no other way, is that to be acquired." (*Home on Strictures.*)

CURE OF STRICTURES BY THE POTASSA FUSA.

Mr. Whately, in his publication on strictures, has endeavoured to shew, that they are not merely contracted fibres of the urethra, but really diseased portions of the membrane lining that canal, with a continued disposition to increased contraction. Hence, this gentleman seems to conceive, that the application of a remedy, calculated both to remove the diseased affection, and to dilate the contracted part, might perfectly cure the complaint, without putting the patient to the inconvenience of wearing a bougie. Mr. Whately affirms, that such a remedy is caustic, when judiciously used. Hitherto the lunar caustic has been chiefly employed; but, this gentleman states, that it has been his good fortune to discover a more efficacious, and, at the same time, a less painful and hazardous remedy for the disease in question. The potassa fusa is the application alluded to, which Mr.

Whately says, if used in the manner, and with the precautions about to be described, will be found to possess singular efficacy in curing the complaint. He avows, that he has already had so much experience of it, and that he is so perfectly convinced of its superiority over the lunar caustic, as well as over the common bougie, that he now uses it in a considerable number of the cases, which come under his care. Of its safety he is also as well convinced, as of its efficacy; for, if used with circumspection, experience shews, that there is little danger of its producing any disagreeable effect.

However, if the potassa fusa be applied while the parts are in a highly inflamed, or irritable state, or (as Mr. Whately adds) tending to gangrene; if the habit be bad, and the patient very far advanced in years; we may expect the most mischievous effects from the application; and this practitioner censures the use of any kind of caustic under such circumstances, for strictures in the urethra, as dangerous in the extreme.

Mr. Whately represents, that if the patient be affected with fever, or any other acute disease; if he be much indisposed from any cause; if, in particular, he have a gonorrhœa, attended with much inflammation and irritation in the urethra; if the prepuce, glans, or any other part of the penis, or the parts adjoining to it, be swelled and inflamed; if the urethra, and especially the strictured part of it, be so irritable, as not to bear the touch of a bougie; the use of the caustic is for the present forbidden. Mr. Whately also enjoins great caution in applying this remedy to persons advanced in years. Even when no objections of the above kind exist, the caustic should not be resorted to in the first instance. Mr. Whately maintains, that in every case of stricture, before venturing to employ the caustic, we ought to be able to pass into the bladder a bougie, of at least a size larger, than one of the finest sort. This is necessary, both to enable us to apply the caustic to the whole surface of the stricture, and to relieve a retention of urine, should it occur during the use of the caustic.

When a bougie of the preceding description can be introduced, without occasioning pain, faintness, or great dejection of spirits, the use of caustic may commence immediately, when none of the above described objections exist.

When the urethra is very irritable, Mr. Whately recommends a common bougie to be introduced every day, and kept in the urethra; at first, for a few minutes only; but, by degrees, for a longer time; till the irritability of the parts has been sufficiently lessened.

When the urethra is rendered so im-

pervious by a stricture, that a small bougie cannot be passed into the bladder, which viscus is also in a painful inflamed state, Mr. Whately asserts, that caustic, in any form, or quantity, must not be immediately employed; but, that the stricture should be first rendered capable of allowing a bougie a little larger, than one of the finest size, to be introduced into the bladder. When this is done, the urine is more freely evacuated, and the consequent irritation and inflammation of the bladder lessened, if not removed, together with the danger of a retention of urine. Caustic may then be advantageously conveyed into the centre of the stricture.

Mr. Whately considers the practice of at once thrusting down, in this sort of case, an armed bougie, considerably larger than the narrowest part of the contracted canal, as most dangerous, and horridly painful. For, says this gentleman, it frequently happens, that nearly the whole of the urethra anterior to the bulb is so much contracted by numerous and uncommonly rigid strictures, that, it is impossible, by any art whatever, to dilate the passage to its natural size. If, therefore, the canal, whilst in such a state, be rudely torn open by a large caustic bougie, hemorrhage, pain, dangerous suppressions of urine, inflammation, mortification, and death itself, must sometimes inevitably ensue,—even before the caustic can be applied to the principal seat of the disease. In cases, like the one just mentioned, the first step, preparatory to the use of the caustic, should be, according to Mr. Whately, to dilate the strictured part of the urethra; for which purpose, he advises the slow and gentle introduction of a fine bougie, with its point inclined to the lower side of the canal, in order to avoid the large lacunæ, situated on its upper part. When the surgeon, by steady perseverance and dexterity, has succeeded in getting a fine bougie through the worst stricture into the bladder, the instrument should be worn, for a few hours, every day, till the passage is sufficiently dilated to admit a larger one.

Mr. Whately, after explaining, that the potassa fusa ought not to be applied to strictures of the urethra, till a bougie of a proper size can be passed into the bladder; after having pointed out the methods to be taken, before applying this caustic; and enumerated certain cases and circumstances, in which its employment is interdicted; next proceeds to describe the mode of practice, which it is the particular object of his book to recommend.

For the purpose of arming a bougie, Mr. Whately advises us to put a small quantity of potassa fusa upon a piece of

strong paper, and to break the bit of caustic with a hammer into small pieces of about the size of large and small pins' heads. In doing this, care should be taken not to reduce it to powder. Thus broken, it should be kept for use in a phial, closed with a ground stopper. The bougie should have a proper degree of curvature given to it, by drawing it several times between the finger and thumb of the left hand.

Mr. Whately next acquaints us, that before the caustic is inserted into the bougie, it is necessary to ascertain the exact distance of the stricture, (to which the caustic is to be applied) from the extremity of the penis. For this purpose, the bougie, which should be just large enough to enter the stricture with some degree of tightness, ought to be gently introduced into the urethra; and when its point stops at the stricture, which it almost always does, before it will enter it, a notch is to be made with the finger-nail, on the upper or curved portion of the bougie, on the outside of the urethra, exactly half an inch from the extremity of the penis. When the bougie is withdrawn, a small hole, about the sixteenth part of an inch deep, should be made at the extremity of its rounded end. A large blanket-pin two inches and a half in length, with the head struck off, will answer the purpose; the hole being made with the point of the pin. The extremity of the bougie should then be made perfectly smooth with the finger and thumb, taking care, that, in doing this, the hole in its centre be not closed. Some of the broken caustic should then be put on a piece of writing paper, and a piece less in size, than the smallest pins' head, should be selected; the particle, indeed, says Mr. Whately, cannot be too small for the first application. Let this be inserted into the hole of the bougie with a pocket-knife, spatula, or some such instrument; and pushed down into it with the blunt end of the pin, so as to make the caustic sink a very little below the margin of the hole. To prevent the potassa fusa from coming out, the hole should then be contracted a little with the finger, and the remaining vacancy in it is to be filled with hog's lard. This last substance (continues Mr. Whately) will prevent the caustic from acting on the sound part of the urethra, as the bougie passes to the stricture. When the bougie is quite prepared, let it be first oiled, and immediately afterwards introduced, by a very gentle motion, with the curvature upwards, as far as the anterior part of the stricture, upon which the caustic is to be applied. In doing this, the end of the bougie, that is held by the finger and thumb, should be a good deal inclined towards the abdomen,

on the first introduction of the instrument, in order to preserve its curvature. After it has passed about five inches, this end should be gradually brought downwards, as the bougie passes on, till it forms a right angle with the body. The bougie is known to have arrived at the stricture by the resistance made to its progress.

As soon as the bougie has reached the anterior part of the stricture, it should rest there for a few seconds, that the caustic may begin to dissolve. It should then be pushed very gently forward, about one-eighth of an inch; after which, there should be another pause, for a second, or two. The bougie should then be carried forward in the same gentle manner, till it has got through the stricture. The sense of feeling will generally inform the operator when the point of the bougie has proceeded so far; but, the notch in the bougie is to be an additional guide, by becoming very near the orifice of the urethra, when the end of the instrument has just got through the stricture.

The bougie should now be immediately withdrawn by a very gentle motion to the part, at which it was first made to rest awhile. Then it should be very slowly passed through the stricture a second time; but, without letting the bougie stop in its passage. If the patient complain of pain, or be faint, the bougie should be immediately withdrawn; but, if these effects are not produced, we may repeat the operation of passing and withdrawing the bougie through the stricture once or twice more, before we finish the operation, which will take up, in the whole, about two minutes.

The first application of the potassa fusa, in this manner, gives, according to Mr. Whately's account, a very little pain. A slight scalding in making water, and a trifling discharge, during the first day or two, however, are commonly produced.

At the end of seven days, the application of the caustic is to be repeated in the same manner. When the first application has enlarged the aperture of the stricture, which may be known by passing a bougie through it, of the same size as that by which the caustic was conveyed, the bougie used in the second operation, should be a size larger, than the one, used in the first; but it must not be too large to pass through the stricture. If the patient had no pain on the first application, the bit of potassa fusa may also be trivially larger. At the end of seven days more, the armed bougie should be introduced a third time. At this, and all future applications, the bougie should be increased in size, in proportion as the aperture in the stricture becomes dilated. The quantity of caustic, however, is never to be in-

creased in a ratio to the size of the bougie. In no cases whatever, does Mr. Whately apply more of the potassa fusa at a time, than a piece about the size of a common pin's-head. Twelve bits of the largest size, which this gentleman ever uses, weigh one grain.

When there are several strictures, the potassa fusa should be generally applied to only one at a time.

An interval of seven days is what Mr. Whately generally allows to elapse between the applications of the caustic. The rule, however, may now and then be deviated from; but, the potassa fusa ought never to be re-applied, till the action of the last application has completely ceased. In a few instances, the interval may only be five days; in some others, it may be eight, nine, or even a longer space.

In the above method of using the potassa fusa, Mr. Whately represents, that this substance is equally diffused over every part of the strictured surface, and only *abrades* the membrane of the stricture, without producing a slough. The *degree* of this abrasion, he says, may be increased, or lessened, as circumstances dictate, by paying attention to the quantity of the caustic.

The foregoing account will suffice for conveying an adequate idea of Mr. Whately's method. I am sorry I cannot add my favourable opinion of the practice. To *abrade*, without destroying, is to me perfectly unintelligible. Nor can I conceive, that a liquid caustic (for so it is represented as becoming) can be applied with the accuracy to strictures, which Mr. Whately seems to suppose happens. This however is merely my own sentiment; and I do not wish to conceal that there are yet a few surgeons who believe, that Mr. Whately's plan is the most eligible for all cases, in which the stricture is irritable, or far advanced. (See *Howship's Pract. Obs. on the Diseases of the Urinary Organs*, p. 207.)

Upon the whole I may safely declare, that caustic bougies are now much less frequently used by the best surgeons in London, than they were about ten years ago. Several distinguished practitioners, who to my knowledge were then accustomed to recommend and employ them, have at present returned either to the use of common bougies, or those made of flexible metal or elastic gum, to which after many comparative trials, I acknowledge, a general, but not universal, preference seems to me to be due. We learn from M. Roux, that caustic bougies never had many advocates in France; and the enquiries, which he made when he was in London, authorized him to announce to his countrymen after his return, that such instruments are at present not more recommended here,

than they are at Paris. (See *Voyage fait à Londres ou 1814, ou Parallèle de la Chirurgie Angloise*, &c. p. 315.)

Cases of stricture however, where the disease is far advanced, of long standing, and attended with such obstruction, that no kind of common bougie can be introduced, appear to me to be the examples, in which the employment of bougies, armed with the nitrate of silver, ought principally to be continued. This mode is certainly less violent, than that of employing a common bougie with sufficient force to make its way through the stricture by exciting ulceration. It must also be attended with less risk of rupturing the urethra, and producing a false passage. I have already explained, that the armed bougie has likewise been particularly recommended for what has been termed the irritable stricture.

The works, which contain the chief information on the subject, which we have just been treating of, are: *A Treatise on the Venereal Disease*, by John Hunter. *Practical Observations on the Treatment of Strictures in the Urethra and Œsophagus*, by Sir Everard Home, in 2 vols. *An improved Method of treating Strictures in the Urethra*, by Thomas Whately, Edit. 2, 1806.

The following works may likewise be consulted: *Howship's Practical Obs. on the Diseases of the Urinary Organs*, particularly those of the bladder, the prostate gland, and urethra, 8vo. Lond. 1816. *Soemmering Abhandlung über die Schnell und Langsam tödtlichen Krankheiten der Harnblase und Harnrohre bey Männern im hohen Alter*. 4to. Frankf. 1809. *Letters concerning the Diseases of the Urethra*, by C. Bell, 1810.

URETHRA, FALSE PASSAGE IN.

One of the worst consequences, of using catheters, and bougies, in an improper manner, is the rupture of the urethra, or the formation of a false passage by ulceration. With bougies, this accident is generally occasioned by trials to excite ulceration by the application of the end of the bougie to the stricture, when this instrument cannot be passed through it. When once the new passage has been formed, whenever the bougie is introduced, it cannot be hindered from going into the false track, and its action on the stricture is altogether frustrated.

Mr. Hunter has advised the following operation to be practised in this kind of case. Pass a staff, or any such instrument into the urethra, as far as it will go, which will probably be to the bottom of the new passage, and this, we may be certain, is beyond the stricture. Feel for the end of the instrument externally, and cut upon it, making the wound about an inch long, if the disease be before the scrotum; and an inch and a half, or more, if in the perineum. If the new passage be

between the urethra and body of the penis, you will most probably get into the sound urethra, before you come to the instrument, or new passage. If so, introduce a probe into the urethra, through the wound, and pass it towards the glans penis, or, in other words, towards the stricture. When it meets with an obstruction, this must be the stricture, which is now to be got through, and afterwards dilated. To complete the operation, withdraw the probe, and, instead of it, introduce a hollow cannula forwards to the stricture. Then introduce another cannula from the glans downward, till the two tubes are opposite each other, having the stricture between them. An assistant is now to take hold of the urethra on the outside, with his finger and thumb just where the two cannulae meet, in order to keep them in their places. Through the upper cannula next introduce a piercing instrument, which is to perforate the stricture, and enter the lower cannula. The piercing instrument is now to be withdrawn, and a bougie introduced through the first cannula and stricture, into the second cannula. The tubes are to be withdrawn, and the end of the bougie, in the wound, directed into the bladder, through the further portion of the urethra. It may also be necessary to lay the whole of the false passage open, in order to make it heal; for otherwise, it might still obstruct the future passage of bougies into the proper canal.

When the new passage is between the skin and urethra, the surgeon must extend his incision more deeply, for the purpose of finding out the natural passage. Then he is to proceed as above explained.

The longer the first bougie is allowed to remain in the canal, the more readily will the second pass. The bougies must be gradually increased in size, and used till the wound is healed. The only improvement, which seems proper to be made in this plan, is to employ hollow bougies, or flexible gum catheters, which might be worn longer than common bougies, as the patient could void his urine through them. (See *Hunter on the Venereal Disease*.)

URINARY ABSCESES. Extravasations of urine may be in three different states. This fluid may be collected in a particular pouch; it may be widely diffused in the cellular membrane; or, lastly, it may present itself in a purulent form, after having excited inflammation and suppuration in the parts, where it is situated. This case is termed by the French writers an urinary abscess.

Such extravasations of urine always imply a rupture in some of the excretory

passages for this fluid, either in the kidneys, or ureters, the bladder, or the urethra. This solution of continuity may be produced by a variety of causes. It is most frequently the effect of a forcible distention of these passages, in consequence of a retention of urine. Phlegmonous abscesses, formed in the thickness of the parietes of these passages, or along their course, may also occasion this rupture, by bursting internally. The solution of continuity may also be produced by a sword, or another foreign body that has penetrated the parts. There are likewise examples of effusions of urine depending upon the displacement of the cannula of the trocar, after the operation of puncturing the bladder. Several have been noticed, (and, indeed, they are very frequent) caused by false passages in the urethra; and we have cases of similar effusions, following violent contusions of the perineum, attended with laceration of the urethra.

In *Les Œuvres Chirurgicales de Desault par Bichat, Tom. 3.* it is further observed, that the ravages, which the urine makes when out of its natural receptacles, are usually greater, and more extensive, when this fluid is extravasated in the cellular membrane, than when it is effused into a particular pouch. The mischief is also less, when the excretory passage is free, than when it is closed by any obstacle, as in cases of retention. The more or less loose texture of the parts, in which such effusions happen, likewise makes a considerable difference in their progress and formation. With regard to the place, which they occupy, it is ordinarily determined by the situation of the rupture, by which the urine has escaped. When the pelvis, or infundibulum of the kidney, or the upper part of the ureter, gives way, the urine is commonly effused in the loins and the fossæ iliacæ, between the peritoneum and the adjacent parts. When the lower part of the ureter, or the bladder, near its lower portion, gives way, the extravasation is generally included within the pelvis.

But, when the rupture occurs in the anterior parietes of the bladder, near its upper part, and, especially, when it takes place at a time, when this organ is extremely distended and dilated, the urine becomes effused behind and above the pubes, sometimes ascends to the epigastric region, between the peritoneum and the abdominal muscles, and, after having followed the course of the spermatic vessels, it often makes its exit at the ring, and is extravasated in the groins and scrotum. If the rupture has happened in the urethra, the most common situation of the effusion is in the perineum and scrotum. The extravasation frequently

extends to the penis and upper part of the thighs, and even sometimes propagates itself, under the skin of the abdomen, up to the hypochondria and sides of the chest. Such is the ordinary course of the urine, when extravasated out of the parts, which are destined to contain it; but, the slightest circumstance may alter this course, and produce sinuses in several other parts of the body.

In the animal economy, there is no fluid, the extravasation of which is so fatal, as that of the urine. If it is not promptly discharged, it soon excites a putrid supuration in the cellular membrane, which contains it, makes this part slough, causes a gangrenous inflammation of the skin, and almost always produces a mortification of the parts, amongst which it flows.

While the extravasation of urine is confined to the interior of the pelvis, and lumbar and iliac regions, without manifesting itself externally, there is no certain sign of its existence. The circumstances, which may be recollected, however, joined with the symptoms, which the patient complains of, may lead to a suspicion of the extravasation. Thus, when in consequence of a retention of urine in the ureters, or bladder, the patient has suddenly experienced great relief, without any of the urine having been discharged the natural way; when he has at the same instant felt a kind of pricking in the loins, or pelvis; when to the ease, which lasted only a few hours, symptoms, more severe than the former ones, have succeeded, such as ardent fever, hiccough, vomiting, &c. there is reason for believing, that an internal extravasation has happened. The uncertainty in the diagnosis is here not much to be lamented, since art can do nothing for this kind of disorder, and, if there were the clearest proofs of its existence, we should be equally compelled to abandon the patient to the resources of nature, whose efforts are almost always ineffectual.

This uncertainty in the diagnosis disappears as soon as the extravasation becomes apparent externally. The case is then announced by symptoms, which hardly ever deceive. The preceding retention of urine; the sudden appearance of the swelling caused by this fluid; the rapid progress of this tumour; the kind of crepitation perceptible in it, like that which occurs in emphysema; the tension of the œdematous shining skin, as in leucophlegmasia; the diminution of the symptoms depending upon the retention; such are the first occurrences, which are observable, when the extravasation is somewhat considerable.

If the patient is not speedily assisted, and the urine continues to be extravasated,

the tumour spreads more and more; the skin assumes a red violet colour; gangrenous eschars are formed, the separation of which gives issue to a very fetid sanies, in which the smell of urine is readily distinguishable. Portions of dead cellular membrane are presently discharged together with the sanies; the ulcer grows larger; and the dressings are continually wet with the urine.

The indications to be fulfilled are not the same in all cases of extravasations of the urine; they vary according to the situation of the breach of continuity in the urinary passages, and the particular situation and extent of the effusion. When the rupture has happened in the ureters, and an urinary abscess is formed in the loins, the aid to be derived from surgery is limited to making an opening in the extravasation, as soon as it can be felt externally. It is then not in the power of art to re-establish the natural course of the urine, or to hinder this fluid from passing through the wound, and rendering it fistulous. However, there are some circumstances, in which a radical cure may be effectually attempted. For example, if the abscess were produced by a calculus lodged in the infundibulum, or ureter, and it could be felt, and taken hold of with a pair of forceps, introduced into the opening, the extraction of the foreign body might promote the healing of the ulcer, by rendering the natural channel for the urine free.

When the opening, by which the urine has become extravasated, exists in the bladder, or urethra, one indication, that does not present itself in the foregoing case, may be fulfilled, viz. the urine may be drawn off by means of a catheter passed into the bladder, and kept there. By this means, we not only immediately stop the progress of the extravasation, but attack the very cause of the malady, by removing the obstacles, which oppose the natural course of the urine. The introduction of the catheter then becomes a matter of the most urgent necessity. This operation is often attended with the greatest difficulties. Besides the ordinary obstruction of the canal, we have also to surmount the obstacles, which the urinary swellings situated in the course of the urethra, create to the passage of the instrument. When these tumours are considerable, they ought to be opened before the catheter is employed. The subsidence of the swellings would render catheterism more easy. Besides, Bichat and Desault were assured by daily experience, that with a little skill, exercise, and patience, the catheter may always be got into the bladder. If, however, the thing could not be done, ought we to puncture the bladder, or have re-

course to the operation termed by the French *boutonnière*?

Desault was an advocate for neither of these proceedings: he thought it was a more simple and beneficial practice merely to make an external opening in the collection of effused urine. This measure would both afford an outlet for the urine, and arrest the extension of the extravasation. Besides, such an opening is often indispensably requisite for the purpose of putting a stop to the symptoms depending upon the effusion and stagnation of the urine. But, if the catheter can be introduced, there may be cases, in which an opening would not only be useless, but hurtful; for instance, when the swelling, caused by the urine, is of little extent, or when it is situated in the thickness of the parietes of the passage, or along its track, it almost always admits of dispersion by the simple employment of the catheter. It seldom happens, however, that this swelling, however small, ends in resolution; it almost always suppurates; but, as it breaks into the urethra, the matter escapes between this canal and the catheter, and renders the making of an external opening needless. Experience teaches us, also, that when the tumour is situated in the scrotum, or between the root of the penis and the symphysis pubis, even after the healing of the incisions, made in these situations, a fistula will often remain, which is very difficult of cure. With the exception of these particular cases, Desault was an advocate for opening all urinary abscesses.

The manner of opening such collections varies according as the urine may be in one cavity, or widely effused in the cellular membrane. In the first case, a simple incision, the whole length of the cavity, will suffice for emptying and healing it. In the second, if the extravasation is extensive, the incisions must be multiplied. It would be absurd to spare the parts; for, all those, with which the urine has come into contact, seldom escape mortification. The incisions, which are made, hardly ever have the effect of saving them; but, by accelerating the discharge of putrid sanies and stagnant urine, they prevent the mischief, which would originate from their further lodgment. If these incisions, however, were practised a few hours after the extravasation, and before suppuration, the parts might be completely freed from urine and preserved. When the operation is at all delayed, their destruction is inevitable. The approach of mortification is indicated by the crepitation under the bistoury, resembling the kind of noise produced by tearing parchment. The extent and depth of the incisions must be proportioned to those of the abscess. When the extravasation occupies the scrotum,

long deep scarifications should be made in that part, as well as in the skin of the penis, and in every place, where the urine is effused.

Practitioners, unaccustomed to see such diseases, would be alarmed at the extent of the sore produced by the separation of the eschars. Sometimes, the whole scrotum, skin of the penis, and that of the groins, perinæum, and upper part of the thigh, mortify, and the naked testicles hang by the spermatic cords, in the midst of this enormous ulcer. It is hardly conceivable how cicatrization could take place over the exposed testicles; but, the resources of nature are unlimited. She unites the testicles and the cords to the subjacent parts, and drawing the skin from the circumference to the centre of the ulcer, she covers these organs again, and furnishes them with a sort of new scrotum. This statement is founded upon numerous cases, in which nature always followed this course. The cicatrization of the ulcer is even more expeditious, than might be apprehended, considering its extent. In all this business, what does art do? If the introduction of the catheter is excepted, which, indeed, is absolutely necessary for the radical cure, her assistance is very limited, and almost nothing, in the generality of instances; for, when the patients are not exhausted by the tediousness of the disorder, when they are of a good constitution, and in the prime of life, they get well as quickly and certainly, with the aid of a good diet and simple dressings, as when they take internal medicines, and use a multiplicity of compound topical applications. The practice of Desault at the Hôtel-Dieu consisted in applying emollient poultices, until the sloughs were detached. The ulcer was then sometimes dressed with pledgets charged with styrax; but frequently mere dry lint was used, and continued till the cure was completed. If any complication occurred in the course of the treatment, suitable remedies were prescribed for it. Thus when prostration of strength, and tendency to sloughing existed, bark, cordials, and antiseptics were ordered. But, in every case, the catheter is the essential means of cure; without it, the treatment is almost always imperfect, and the ulcer will not heal, without leaving several urinary fistulæ. (See *Œuvres Chirurgicales de Desault par Bichat*, Tom. 3, p. 277—287.)

URINARY CALCULI. The causes of the precipitation of the salts, which the urine holds in solution, and of the formation of urinary calculi, are totally unknown. The conjectures, which have been entertained upon this subject, respecting the effect of certain kinds of food, drink, air, &c. do not appear to be built upon any good foundation. According to Delpech,

the following is all the exact knowledge that we have upon this interesting topic.

1. If a foreign body be introduced into a cavity, which is naturally a receptacle for the urine, whatever may be the nature of the immersed substance, it is sure to become incrustated with the urinary salts, without any change, however, in its composition. In this case, there is manifestly no chemical combination, but merely an irregular precipitation of the saline particles, in consequence of the attraction of aggregation. Nor is there in this instance the least reason for suspecting the operation of any peculiar diathesis in producing the calculus, since the introduction of the foreign body, which forms the nucleus for it, occasions the same consequence in all descriptions of patients.

2. There are countries, where calculi are exceedingly common: others, where the formation of these extraneous substances is very rare; and yet one cannot explain the difference by any geographical circumstance, which is constant; nor by any remarkable particularity in the constitution of the inhabitants.

3. Calculous patients may likewise be perfectly healthy in every other respect, if the effects of the calculi have not materially injured the urinary organs.

4. Subjects, gifted with the strongest constitutions, are liable to urinary calculi, quite independently of the accidental introduction of any foreign body into the urinary organs. In these cases, probably, the origin of the complaint may be ascribed to a particular diathesis not at all understood.

5. A sort of connexion between gout, the formation of urinary calculi, and hemorrhoids, has been suspected, and these complaints have been thought frequently to succeed, and, as it were, mutually replace each other. The cases on record tending to such a conclusion are not numerous, and as they are not sufficiently uniform in their progress and results, the inference is not clear, nor even probable. The observations only prove the concurrence of those affections in the same individual. Besides, this pretended analogy seems rather to be founded on a forced resemblance of gouty concretions to urinary calculi, than upon direct observation; but, analysis demonstrates, that these substances are totally different in their composition.

6. It is alleged, that women are less subject than men, to urinary calculi; but our researches upon this subject still leave it doubtful, whether women are in reality less liable to the disorder, or only suffer less frequently from it, in consequence of the facility with which the calculi are generally discharged through the short and capacious urethra of the female subject.

7. Childhood and infancy present numerous instances of urinary calculi; but, at these periods of life, relapses are seldom observed; that is to say, an entirely fresh stone is hardly ever formed again. If a return of the complaint happens, the quickness of the recurrence, and an attentive examination of the calculus, will in general sufficiently prove, either that the stone has formed round a fragment, which had not been extracted in the previous operation, or that it was already completely formed at the same period.

8. Youths and adults are very seldom troubled with calculi, even though they may have been thus afflicted in their infancy or childhood.

9. Old men are much more liable to the disorder; and, in them, the disposition to it continues throughout life. Hence, relapses in such patients are very common.

10. Chemical analysis has proved, that urinary calculi contain and have for their basis a kind of animal matter, besides different salts, the bases of which are lime, ammonia, magnesia, soda, and silica, and a peculiar acid, termed *uric*, or *lithic*. There is no urinary calculus, in which such animal matter cannot be found, having the size and shape, which the calculus itself had previously to its dissolution. (*Delpech, Précis Élémentaire des Maladies Chir. Tom. 2, p. 193, &c.*)

Authors usually divide urinary calculi into those, which are situated in the kidneys, or ureters, and termed *renal*, and into others, which are lodged in the bladder, and called *vesical*. The symptoms and treatment of cases of calculi in the kidneys and ureters are rather medical, than surgical subjects, and I shall therefore not describe them in the present article. Some reflections, however, upon the operation for the extraction of renal calculi, have not been omitted. (See *Nephrotomy*.)

It is thought, that the greater number of urinary calculi originate from concretions formed in the kidneys, and brought down into the bladder by the ureters. The cases, however, in which the calculi are formed round foreign bodies introduced into the bladder through the urethra, the digestive organs, or some accidental wound, must be regarded as exceptions to the preceding observation. In the centre of urinary calculi, surgeons have often met with bullets, splinters of bone, bits of wood, pins, &c. It is not necessary for such foreign bodies to be large, in order to produce this effect: a clot of blood, or a little bit of straw, is sufficient to cause a precipitation of the urinary salts, if it be not very soon voided.

A urinary calculus, thus produced, is always single, unless several foreign bodies have been introduced into the bladder.

But, when urinary calculi originate from a particular diathesis, several are often present together. Several distinct nuclei may descend successively from the kidneys, and each may attract new depositions, and separately increase. Sometimes, however, several calculi, which at first were separate, are afterwards cemented together, so as to constitute only one.

The magnitude of urinary calculi is generally in an inverse ratio to their number. Some hundreds have been found in the same bladder; but, they were not larger than a pea. Others of so large a size have been met with, that their greatest diameter was more than six inches. Their average size may be compared with that of a chesnut, a walnut, or small hen's egg. Their weight differs from a few grains to upwards of fifty ounces. Common urinary stones, however, weigh from two to six ounces. Their weight is not always proportioned to their size. Substances of different qualities may enter into their composition, and diversify their heaviness. Thus, the salts, which have silica for their base, are seldom met with; but, the calculi, which contain them, are much the heaviest, in proportion to their size. On the other hand, some urinary salts crystallize, when precipitated: of this kind is the *ammoniaco-magnesian phosphate*; and the crystals of this salt, when they form a thick layer, intercept spaces, which are not filled up by the subsequent precipitations. (*Delpech, T. 2, Sect. 5.*)

Dr. Wollaston has divided urinary calculi into four species. 1st. The uric acid concretion. 2d. The fusible calculus, or phosphate of ammonia and magnesia. 3d. The mulberry calculus, or that consisting of oxalate and phosphate of lime. 4th. The bone-earth calculus, or that composed of the phosphate of lime.

To these, as we have already stated, must be added another less frequent sort containing silica.

The urinary salts in calculous patients are not always precipitated in the same quantities: indeed, in some cases, the process appears to be suspended, even for a considerable time. Hence, a stone of middling size, already formed, may increase but very slowly; and if the mucous membrane of the bladder be not extremely sensible, the foreign body may only produce slight inconveniences. Thus, a calculus, which could be felt with a sound, has been known to continue more than ten years in the bladder, and after all this time be only of a moderate size. (*Delpech, Précis Élémentaire, &c. T. 2, p. 222.*)

As the same well informed surgeon notices, some examples of the curative efforts of nature, which have occasionally proved successful, can be adduced. A stone of

small size is mostly propelled towards the neck of the bladder, especially when the urine is discharged with celerity; and it has often happened, that the foreign body has been carried into the urethra, through which it has passed, with more or less facility, and been voided with the urine.

Delpech has even cited instances, in which the stone has made its way by ulceration into the vagina, and rectum, or through the perineum. Such cases, however, do not appear to have been examined very particularly; and Delpech is inclined to think, that if a proper investigation had been made, it would have been discovered, that the calculi did not escape from the bladder by ulceration of any part of its fundus, but, that they first passed a little beyond the neck of the bladder, into the urethra, where they lodged, and increased in size until they produced ulceration, or sloughing of the parts.

It has been conjectured, that urinary calculi may sometimes be more or less acted upon by the absorbents; but, there are no instances on record proving, that a stone, indisputably present in the bladder, was ever removed in this way. Nor is it proved, that the properties of the urine ever spontaneously undergo such a change, as will bring about the dissolution of a calculus.

Attacks of pain in the kidney, followed by the usual symptoms of a passage of a renal calculus into the bladder, and then by difficulty and pain in making water, make it probable that the bladder contains a small stone, which may not readily admit of being felt with the sound. When, however, a foreign body is known to have got into the bladder, the diagnosis will be attended with greater certainty. If, under these circumstances, the evacuation of the urine should be suddenly obstructed, and acute pain be felt at some point of the urethra, the calculus has probably entered this passage, and nature is endeavouring to expel it again. Certain information, however, may be immediately acquired by the introduction of a sound. In this sort of case, the impetus of the stream of urine may be augmented, and the resistance of the parietes of the urethra lessened, by mucilaginous drinks, and the warm bath. At the same time, suction, oily injections, and attempts at extraction with wire-nooses, hooks, forceps, &c. have been advised. But, these mechanical means, as Delpech observes, are always attended with danger and uncertainty. The other means, however, may be tried, as long as the accumulation of urine is not very considerable; but, when further delay would be attended with excessive distention of the bladder, or risk of the rupture of its parietes, or those of the urethra, the sur-

geon ought at once to make an incision directly upon the calculus and extract it.

When a small calculus is known, or strongly suspected, to be in the bladder, but it does not spontaneously pass into the urethra, Delpech recommends dilating the passage to the utmost with elastic gum catheters, then a considerable quantity of urine is to be allowed to collect in the bladder, the catheter is to be suddenly taken out, and the patient to make water in as strong a stream as he can. A pin, which had got into the bladder, has been extracted, after long and patient trials, by entangling it in the eye of the catheter. Delpech conceives, that the simple dilatation of the urethra would probably have had the same result.

These means for promoting the natural expulsion of urinary calculi, it is obvious, can only answer when these foreign bodies are very small, excepting in women, in whom the practice may be carried to a greater extent.

As the symptoms of a stone in the bladder are detailed in another part of this Dictionary, it will only be necessary in the present place to refer the reader for information upon that subject, to the article *Lithotomy*, where some observations on encysted calculi will also be found.

The stone being a most severe affliction, and the operation extremely hazardous and painful, a variety of experiments have been instituted, for the purpose of discovering a solvent for urinary calculi. Hitherto, however, all the remedies and plans, which have been tried, have been attended with very limited, and, by no means, unequivocal success, notwithstanding many persons may have been deceived into a contrary opinion.

The dissolution of stones in the bladder has been attempted by lithontriptic medicines, as they have been termed, and by fluids injected into this viscus.

From the experiments of Fourcroy, it appears, that almost every ingredient in calculi is dissolved by the caustic alkali; and various experiments have shewn, that the whole calculus yields to its powers. Limewater has also been found to be a solvent of urinary calculi out of the body. It is obvious, however, that what is taken by the mouth is subject to many changes in the alimentary canal, and also the lymphatic, and vascular systems, and that, in this way, it must be exceedingly difficult to get such substances, (even were they not liable to alterations) in sufficient quantity into the bladder.

Lime was long ago known to be a solvent of urinary calculi, and different methods were employed to administer it with safety. One of these plans fell into the hands of a Mrs. Steevens, and her success

caused great anxiety for the discovery of the secret. At last, Parliament bought the mystery for £5000. In many instances, stones which had been unquestionably felt, were no longer to be discovered; and, as the *same* persons were examined by surgeons of the greatest skill and eminence, both before, and after, the exhibition of the medicines, it is no wonder, that the conclusion was drawn, that the stones had been really dissolved. From the cessation of such success, however, and from its now being known, that stones occasionally become lodged in a kind of cyst, on the outside of the general cavity of the bladder, so as to cause no longer any material suffering, surgeons of the present day are inclined to suspect, that this must have happened in Mrs. Steevens's cases. This was certainly what happened to one of the persons on whom the above medicine was tried, as Dr. W. Hunter informs us. It is evident, that a stone, so situated, would not in general produce a great deal of irritation, nor admit of being felt with a sound; though, as I have stated in the article *Lithotomy*, there have been a few exceptions to this observation.

Mrs. Steevens first gave calcined eggshells alone; but, finding costiveness produced, she added soap. In time, she rendered her process more complicated, adding snails burnt to blackness, a decoction of camomile flowers, parsley, sweet fennel, and the greater burdock.

As soap was with reason supposed to increase the virtues of the lime, it led to the use of the caustic alkali, taken in a mucilage of veal broth. Take of kali prepared, $\mathfrak{z}\text{viij}$; of quick-lime $\mathfrak{z}\text{iv}$; of distilled water $\mathfrak{lbj}$. Mix them well together in a large bottle, and let them stand for 24 hours. Then pour off the ley, filter it through paper, and keep it in well stopped phials for use. Of this the dose is from 30 drops to $\mathfrak{z}\text{ij}$, which is to be repeated, two, or three times a day. Mix the quantity to be used in the day, with three pints of plain broth, made of the lean part of veal, all the fat, or oily parts being separated from the liquor, by skimming them off when cold. Let the patient drink, within an hour, a pint of this broth three times a day; early in the morning, at noon, and in the evening. Continue this plan, for three or four months, living, during this course, on such things as least counteract the effect of the medicine. The common fixed alkali, or carbonated alkali, and the acidulous soda water, have of late been used as lithontriptics. Honey has also been given, and Mr. Home, surgeon at the Savoy, has recorded its utility in his own, and his father's cases. Bitters have likewise been tried.

Of the soap, as much may be taken as

the stomach will bear, or as much as will prove gently laxative; but, of the lime-water few can take more than a pint daily.

The acidulous soda water may be taken in larger quantities, as it is more agreeable. The acidulous salt is now prepared so as to produce this water extemporaneously. It must be swallowed, however, while the salt is dissolving; as the carbonic acid gas escapes with great rapidity.

On the whole, I believe, reason and experience will not allow us to consider limewater, soap, acidulous soda water, caustic alkali, and bitters, as any thing more than palliative remedies, by which the pain of the disorder may be sometimes diminished. For, according to my notions, it seems more rational to impute the few supposed instances of greater success to the calculi becoming encysted.

Medicines, taken into the stomach, having failed to dissolve urinary calculi, solvent injections have been introduced through a catheter directly into the bladder. Fourcroy and Vauquelin ascertained, that a ley of potassa, or soda, not too strong to be swallowed, softens and dissolves small calculi, composed of the uric acid and urate of ammonia, when they are left in the liquid a few days. They have proved, that a beverage, merely acidulated with nitric or muriatic acid, dissolves, with still greater quickness, calculi, formed of the phosphate of lime, and of the ammoniaco-magnesian phosphate. They have ascertained, that calculi, composed of the oxalate of lime, which are the most difficult of solution, may be softened, and almost quite dissolved, in nitric acid, greatly diluted, provided they are kept in the mixture a sufficient time.

We are then acquainted with liquids, which will dissolve calculi of various compositions; but, much difficulty occurs in employing them effectually in practice. For, although we can easily inject them into the cavity of the bladder, this organ is so extremely tender and irritable, that it cannot bear the contact of any fluid, except that which it is destined by nature to contain, and the action of such liquids upon it, as would be requisite for dissolving a stone in its cavity, would produce sufferings, which no man could endure, and the most dangerous and fatal effects on the bladder itself. Another objection to this practice also arises from the surgeon never knowing what the exact composition of a calculus is, before this body is extracted, and his consequent inability to determine what solvent ought to be tried. Upon this, however, it is unnecessary to lay much stress, since if the previous, more weighty objections were done away,

the latter difficulty, might, perhaps, be obviated.

URINARY FISTULÆ. By an urinary fistula, strictly speaking, is implied a deep, narrow ulcer, which leads into some of the urinary passages: but, this name is likewise applied to sinuses, which without having any communication with these passages, terminate near some point of their course. Thus, in Desault's works (*Tom. 3, p. 287*), three kinds of fistulæ, in respect to the urinary passages, are noticed. The first sort is called a *blind external fistula*, because it opens only externally; the second, *blind internal*, because it has only one opening into the urinary passages; the third, is termed *complete*, being attended both with an internal opening into the urinary organs, and one or more external apertures.

Amongst the blind external fistulæ, only such as terminate near the canal of the urethra are particularly noticed in Desault's works. All fistulæ of this kind are originally owing to an abscess, that has formed in the vicinity of the urethra; and, in the article, *Urinary Abscesses*, it has been explained, that these suppurations frequently originate from disease of that canal. Whatever may be the cause of these fistulæ, however, it is not unusual to find, that, after the pus has made its way towards the scrotum or perineum, and discharged itself outwardly, the ulcer is converted into a sinus, which resists all the efforts of nature to heal it. According to Desault, this kind of fistula may be kept up by a thinning and denudation of the parietes of the urethra; a very common disposition, when the abscess is situated about the root of the penis, and towards that part of the canal, which is situated over the scrotum, in consequence of the weight of this latter organ tending incessantly to separate it from the urethra. The opening of the fistula being too small; its orifice higher than its bottom; and its track being narrow and tortuous; may likewise occasion sinuses, and render the sore difficult to cure, by opposing the free exit of the matter. It may also be complicated with hardness and callosities, caries of the bones of the pelvis, disease of the tendons of the muscles of the perineum, &c. It is known, that these different complications operate as so many obstacles to the cure of sinuses. It is easy to distinguish these kinds of fistulæ from such as terminate near the rectum. Besides the symptoms which may be remembered to have occurred, and which are sufficient to point out the difference; a hardness, resembling a cord, that appears to run towards the urethra, may be felt when the finger is passed along the fistulous track. A probe, introduced into the fistula, follows the direction of this cord, and

is at last stopped by the parietes of the urethra. It may also be ascertained, that the sinus has no communication with the urethra, by the following considerations: 1. No urine has escaped from the fistula, nor any purulent matter from the urethra. 2. A probe, when introduced into the sinus, cannot be made to touch a catheter passed into the urethra. These symptoms, however, are not infallible; for, in complete fistulæ, it sometimes happens, when the internal opening is small, and there is no obstruction in the urethra, that the whole of the urine is discharged through this canal. Frequently, also, the probe is stopped in the tortuosities of the fistulous track, and, when pushed against the parietes of the urethra, it does not always penetrate the internal opening, especially when this is small, and it is situated in some point of the denuded portion of the canal, that does not correspond to the direction of the fistula. The issue of a larger quantity of pus, on slight pressure being made along the canal, leaves no doubt of the existence of sinuses. With respect to other complications, such as callosities, caries of the bones, &c. they may be readily ascertained by their proper symptoms.

The indications to be fulfilled in the treatment of these fistulæ, depend upon a knowledge of the different complications. When the sinuses are kept up by a separation of the scrotum from the parietes of the urethra, Desault recommends exact compression to be made over the part, which method, he says, is sometimes sufficient to accomplish a cure. When this plan fails, he states, that the healing of the sinus may be promoted by practising an incision on one side of the scrotum, and carrying it as far as the denuded portion of the urethra. When sinuses exist, and they depend upon the smallness of the opening, or its unfavourable situation for the discharge of the matter, the aperture should be enlarged by making an incision into the main collection of pus. When there are callosities, which resist cataplasms, and the most active resolvents, Desault advises us to introduce into the fistulæ, trochees of minium, for the purpose of destroying the indurated parts. When the bones are carious, and the tendons diseased, exfoliation must be awaited; and, in every instance the treatment should vary, according to the cause, upon which the fistula depends.

Incomplete internal urinary fistulæ, or, in other words, blind internal fistulæ, are seldom met with in the ureters and bladder. The quality of the cellular substance, which surrounds these parts, favours the effusion of the urine too much for the disorder, arising from a breach of con-

tinuity in them to be confined to a simple internal fistula. Such fistulæ, however, are often met with in the urethra. The bursting of an abscess into this canal; the rupture of the same canal in consequence of a retention of urine; a false passage; the healing of the external part of the wound made in lithotomy, while the internal part is not united; are all so many causes of this disease.

The diagnosis of these fistulæ is deducible from circumstances, which may be recollected; together with a discharge of pus from the urethra, before, and sometimes after the issue of the urine; the pressure of a tumour in the course of the urethra, which tumour increases while the patient is making water, and afterwards disappears by pressure, attended with a fresh discharge from the penis of matter blended with urine. This symptom alone is characteristic; for, an old gonorrhœa, complicated with indurations, may also keep up suppuration of the canal. The existence of pain gives no positive information; and nothing certain can be ascertained by the introduction of the catheter. It is true, the beak of this instrument may become entangled in the fistula; but, its entrance into the bladder may equally be opposed by a variety of other obstacles.

These internal urinary fistulæ cannot be cured, except by preventing the urine from getting into them and lodging there. The catheters employed should neither be too large, nor too small. If too large, they would exactly fill the canal, and the pus and urine contained in the fistulæ could not be discharged. If too small, the urine would insinuate itself between them and the sides of the urethra, and enter the fistulæ. Such inconveniences may be avoided by using a catheter of moderate size. Its employment must be continued till the ulcer is entirely healed. The inutility of medicated bougies, and other internal and external remedies, is too manifest to need any comment.

Of all urinary fistulæ, there are none more frequent than those which are termed *complete*. Their origin may be in the ureters, bladder, or urethra. Those which arise in the ureters, sometimes terminate in the colon, and the urine is discharged *per anum* mixed with the feces. But, most commonly, these fistulæ make their appearance externally, either in the lumbar, or inguinal regions. Those which communicate with the bladder, have also different terminations. When they proceed from the upper and interior part of this organ, they ordinarily pierce the parietes of the abdomen above the pubes, and towards the navel. They also sometimes terminate in the groins. When they originate in the posterior

parietes of the bladder, they sometimes tend into the cavity of the abdomen, where they almost always prove mortal; and sometimes into the intestines, if there should be adhesions between these and the bladder so as to favour this communication. When the opening in the bladder is near the bottom of this viscus, the fistula sometimes terminates in the rectum of the male, and the vagina of the female subject; but, most frequently, it ends in the perineum, in both sexes. With regard to the fistulæ, which originate in the urethra, they usually open externally in the perinæum, the scrotum, or the penis, and sometimes also in the rectum. It is not uncommon to see the external opening of these fistulæ at a great distance from the internal one, and to find it in the middle, and even the lower part of the thighs, the groins, parietes of the abdomen, and as high as the sides of the chest. Often there is only one opening in the urethra, while there are several situated externally, more or less distant from one another.

Most of these fistulæ are the consequences of a retention of urine, and are owing to the same causes, as the diseases of which they are a symptom. Those which communicate with the rectum, in the male subject, sometimes depend upon this intestine having been wounded in the operation of lithotomy; and those, which open into the vagina, are often the effect of a violent contusion, caused by the head of the child in difficult labours, or of ulceration produced by pessaries, which are too large, and the margins of which are too sharp and irregular. Carcinoma of the rectum and vagina also give rise to fistulæ, by extending into the bladder.

The discharge of urine from the external orifice of the fistula is an unequivocal proof of its communication with the urinary passages; but this symptom does not always exist, and, it often happens, that, when the fistula is narrow, and there is no obstruction in the urethra, the urine more readily escapes the latter way, than through the fistula. The kind of cord, which is felt in the track of the fistula, and which extends towards the urethra, is a very uncertain criterion of the communication with this canal. This symptom is common to all fistulæ complicated with callosities, whatever may be their nature in other respects. The fungus, which sometimes appears round the external orifice, is also observed in fecal fistulæ. The situation of this outer aperture scarcely affords any presumption on the nature of the fistula, since, in numerous cases, this opening is very distant from the urinary passages. When the fistula is narrow and tortuous, injections will not always pass into the blad-

der or urethra, but become extravasated in the cellular substance. It is often difficult, sometimes even impossible, to find out the internal orifice of the fistula with a probe. When it communicates with the rectum, or vagina, the opening may sometimes be perceived with the finger, and occasionally, a staff introduced through the urethra, may also be felt in those parts. When the fistula originates in the bladder, the issue of the urine is continual; and when it arises in the urethra, the discharge of this fluid is only made, when the patient has occasion to make water. This distinguishing sign is not constant, and, in Desault's works, mention is made of several cases, in which the urine did not issue from fistulæ communicating with the bladder, except when the patients endeavoured to empty that organ.

Fistulæ of the kidneys, or ureters, are entirely beyond the reach of art, unless they should be kept up by the retention of urine in the bladder, or the presence of a foreign body in the track of the fistula. The re-establishment of the natural course of the urine, and the extraction of the extraneous substance may, in such a case, effectually contribute to the cure. Here, however, we have no certain means of preventing the urine from entering the fistula. This is not the case, with respect to fistulæ of the urethra, where we are, as it were, masters of that fluid. It is particularly in these latter disorders, that elastic gum catheters are attended with inestimable advantages.

When fistulæ of the bladder, or urethra, are the consequences of a retention of urine, produced by obstructions in this last canal, these obstructions often exist still; sometimes they have even increased since the formation of the fistula, which circumstance, in the majority of cases, renders the introduction of the catheter extremely difficult.

It is particularly when fistulæ terminate in the lower part of the bladder, that the utmost care must be taken to prevent the catheter from being stopped up by any foreign body, which would obstruct the urine, as well as to hinder the instrument from becoming displaced, or slipping out of the bladder. Perhaps, in this instance, instead of stopping up the catheter, it would be better to keep it constantly open, in order to prevent all accumulation of urine in the bladder, and the passage of this fluid through the fistula. But, when the fistula communicates with the urethra, no advantage would be derived from keeping the catheter open, and the treatment would be more painful and unpleasant to the patient.

In both cases, Desault recommends us

to continue the employment of the catheter, not only until the fistula is cured, but also until the obstacles, which hinder the urine from passing the natural way, are removed. If, besides, there should exist any of the complications, spoken of in treating of blind external fistulæ, the methods there advised are to be pursued; but, in general, the catheter will suffice to effect the cure. Certain fistulæ, however, demand a particular mode of treatment. Such are those, which form communications between the bladder and the rectum, or vagina.

Fistulæ of the bladder, communicating with the vagina, and produced by difficult labours, are almost always attended with loss of substance. The forcible contusion occasioned by the child's head on the anterior parietes of the vagina and bottom of the bladder, gives rise to the formation of sloughs, the separation of which sometimes leaves apertures large enough to admit the finger, and hence the cure is exceedingly difficult. In treating such fistulæ, there are two indications to be fulfilled; 1st to keep the urine from passing into the vagina: 2dly. to keep the edges of the division as closely as possible together, so as to give them an opportunity of uniting.

The first of these indications demonstrates more and more the utility, and even the necessity of the catheter. In women, its introduction is easy; but in them it is more difficult to fix the instrument, than in men. Desault contends, however, that it is very essential to have it favourably fixed in the bladder, so that the urine may escape, immediately it arrives in this viscus. None of the means hitherto employed, seemed to Desault to answer this purpose completely. This eminent surgeon found, that the only effectual plan was to fasten the catheter to a point, that always retained the same position, with respect to the meatus urinarius. He used a kind of machine made after the manner of a truss, the circle of which was long enough to embrace the upper part of the pelvis, and had in its middle an oval plate to be placed upon the pubes. In the centre of this plate was a groove, to which a piece of silver was fitted, curved so that one of its ends having an aperture in it, came over the vulva, on a level with the meatus urinarius. This piece of silver admitted of being fastened to the plate with a screw. After having introduced, and arranged the catheter in the bladder, so that its beak and eyes may be situated at the lowest part of this viscus, the end of the instrument is to be put through the aperture of the piece of silver, which slides in the groove of the plate, and it is afterwards to be fixed in the way already

explained. By means of this machine, the catheter is invariably fixed, without incommoding the patient even when she is walking.

In this disease, large catheters with full sized apertures should be employed, so that the urine may more readily escape through the instrument, than fall into the vagina. In the early part of the treatment, the catheters should also be left constantly open.

In order to fulfil the second indication, and keep the edges of the division as near together as possible, Desault advises us to introduce into the vagina, a soft kind of pessary, large enough to fill the vagina, without distending it. The introduction of this instrument changes the form of the fistula from round to oval, which is the most favourable to its re-union; and it has also the advantage of closing the fistula, and hindering the urine from falling into the vagina. These fistulae often cannot be cured till after much time,—six months, and even a year.

When the rectum is wounded in the operation of lithotomy, an event that may be known both by the escape of the feces through the wound, and the introduction of the finger into the incision, or within the rectum, Desault advises us to divide at once the parts comprehended between the wound of the operation, the opening in the rectum, and the margin of the anus. This, he says, is the means of preventing the feces from passing into the bladder, and the urine into the rectum. This second operation allows the matter to escape readily, and cicatrization taking place from the bottom of the wound, in the direction outward, the patient is cured without any fistula; whereas this last grievance is almost inevitable, when the preceding plan is not adopted early. It deserves attention, that the catheter is then incapable of effecting a cure. It effectually prevents the urine from entering the fistulae; but, it cannot hinder the feces from doing so, which would keep up the disease.

For Desault's particular method of dividing the parts, I must refer to his works. (See *Oeuvres Chirurgicales de Desault par Bichat*, Tom. 3, p. 287—300.)

URINE, INCONTINENCE OF. This complaint is quite the reverse of a retention of urine; for, as in the latter affection, the urine is continually flowing into the bladder, without the patient having the power to expel this fluid; so, in the former, the urine flows out, without the patient being able to prevent the occurrence.

An incontinence of urine may originate from several causes. 1. From the irritation of the neck of the bladder by stones.

2. From a paralysis of the sphincter vesicae, while the contractile power of the muscular coat of the bladder remains in its natural state. 3. From laceration of the parts in the extraction of large stones, and a consequent paralysis of the sphincter after the wound has healed. 4. From the injury, which the parts suffer from pressure in difficult labours.

When an incontinence of urine proceeds from an irritation of the neck of the bladder by a stone, it can only be radically cured by the operation of lithotomy; though great relief may be given by mucilaginous and anodyne medicines, particularly, when given in the form of injections. In the other two cases, in which it is occasioned by a paralytic affection of the sphincter, we can only attempt the cure by such medicines as are proper in other paralytic cases, viz. the Peruvian bark, chalybeates, the cold bath, and other tonics; but, of all topical remedies, cold applications to the perinaeum are found to be the most effectual. The most powerful remedy of this kind is to dash cold water upon the part; though it is sometimes found useful to apply cloths dipped in vinegar and water, or a solution of saccharum saturni, in the acetous acid.

When no relief can be obtained by the above proposed remedies, we must then have recourse to some mechanical method of compressing the urethra, and thus preventing the continual dribbling of the urine, which must always be very disagreeable. A very proper instrument for this purpose is called a *jugum*, or yoke. It ought to be lined with silk or velvet; and, by means of the screw, the pressure may be made greater or lesser at pleasure. For women, we must make use of pessaries. These must be made of sponge, only of such a size as to be easily admitted, and, before they are introduced, they must be moistened with the finest olive oil, which, according to Mr. Latta, most effectually prevents them from becoming soon troublesome by excoriating the vagina. Pessaries, made of wood, can never be used in cases of this kind with effect; for, in placing them in the vagina, so as to compress the neck of the bladder, it is obvious they must at the same time press upon the rectum, and, on that account, prevent the natural passage of the feces. In some particular cases, even these palliative remedies prove ineffectual; for, when the disorder proceeds from an irritation of the neck of the bladder, the patient has such a continual desire to make water, that it is impossible to bear any confinement of it. We can then merely employ proper receptacles for collecting it as it flows. In women these can only be by pieces of sponge, applied externally,

and kept in that situation with a T bandage; but in men, other contrivances may be employed.

In the Medical Observations, we have some surprising instances of the efficacy of blisters in removing this complaint. A girl, thirteen years of age, who, for four years, had been able to retain her water only a very short time in the day-time, and not at all during the night, was cured in twenty-four hours by the application of a blister to the os sacrum. A man, thirty-two years of age, was attacked by this disease, accompanied with a palsy of the lower extremities, in consequence of having taken some virulent quack medicines, probably of the mercurial, or arsenical kind. In twenty-four hours after the application of a blister to the os sacrum, he was able to retain his water for an hour, and in a week afterwards, for two hours. In about a month, he was able to retain it for five hours, and at last obtained a perfect cure. He also recovered in some degree the use of his limbs, which were paralytic. The like good effects were produced on a woman of fifty, in whom the disease had been brought on by a strain. In her it was likewise accompanied with a palsy of the lower extremities, and of this too she got the better. In a woman of forty-three, in whom the disease seems to have come on without any evident cause, the cure was accomplished, almost during the time that the blister was rising. In a young man, who had been attacked with the disease, after lifting a heavy load, a cure was accomplished in sixteen days. A man of forty-four years of age, who had been attacked by the disease, without any evident cause, was in like manner cured on the first application of a blister. This man had likewise symptoms of diabetes; but the blister had no effect in removing them. A boy, ten years of age, had violent complaints in the urinary passage, which were supposed to proceed from an ulcer. "When about to make water, he was obliged to put himself in a prone posture, and then his urine generally came away by drops, with exquisite torture. At length, it began to come away insensibly during the night;" but, by the application of a blister, this incontinence was removed in less than forty-eight hours, the other symptoms remaining as they were. In all these cases, the blisters were very large, covering not only the os-sacrum, but extending from side to side.

URINE, RETENTION OF. It is observed by the experienced Mr. Hey, that a retention of urine in the bladder, when the natural efforts are incapable of affording relief, is, in male subjects, a disease of great urgency and danger.

Persons, advanced in years, are more subject to this complaint, than those, who are young, or middle-aged. It is often brought on by an incautious resistance to the calls of nature; and, if not speedily relieved, generally excites some degree of fever.

It is sometimes attended with a considerable degree of fever, and an inflammatory affection of the bladder, which terminates in a discharge of purulent matter, and a fatal hectic.

The distinction, says Mr. Hey, which has sometimes been made, between a *suppression* and *retention* of urine, is practical and judicious. The former most properly points out a defect in the secretion of the kidneys; the latter, an inability of expelling the urine when secreted.

The *retention of urine* is, an inability, whether total or partial, of expelling, by the natural efforts, the urine contained in the bladder. The characteristic symptom of this disease, previous to the introduction of the catheter, is a distention of the bladder (to be perceived by an examination of the hypogastrium), after the patient has discharged all the urine, which he is capable of expelling.

As this complaint may subsist, when the flow of urine from the bladder is by no means totally suppressed, great caution is required to avoid mistakes on this subject.

Violent efforts to make water are often excited at intervals, and, during these strainings, small quantities of urine are expelled. Under these circumstances, the disorder may be mistaken for the strangury.

At other times a morbid retention of urine subsists, when the patient can make water with a stream, and discharge a quantity equal to that, which is commonly discharged by a person in health. Under this circumstance, Mr. Hey has known the pain in the hypogastrium, and distention of the bladder, continue, till the patient was relieved by the catheter.

And lastly, it sometimes happens, that when the bladder has suffered its utmost distention, the urine runs off by the urethra, as fast as it is brought into the bladder by the ureters. Mr. Hey has repeatedly known this circumstance cause a serious misapprehension of the true nature of the disease.

In every case of retention of urine, which this gentleman has seen, the disease might be ascertained by an examination of the hypogastrium, taken in connection with the other symptoms. The distended bladder forms there a hard and circumscribed tumour, giving pain to the patient when pressed with the hand. Some obscurity may arise upon the examination of a very corpulent person; but, in all

doubtful cases, the catheter should be introduced.

Mr. Hey mentions, that he has seen but a few cases of the *ischuria renalis*, or complete suppression of the secretion of urine by the kidneys. The disease proved fatal in all his patients except one, in whom it was brought on by the effect of lead, taken into the body by working in a pottery. It subsisted three days, during a violent attack of the colica pictorum, and was then removed, together with the original disease. Mr. Hey found no difficulty in distinguishing this disorder, in any of the cases, from the *ischuria vesicalis*, though, for the satisfaction of some of his patients, he introduced the catheter. (*Practical Observations in Surgery*, p. 374, &c.)

Ischuria, or retention of urine, may be the effect of a great many different causes. We shall proceed to take notice of the causes, which are produced by a paralysis of the bladder; by inflammation of its neck; by foreign bodies in it; by pressure made on it by the gravid uterus; by an enlargement of the prostate gland; and by strictures in the urethra.

1. OF THE RETENTION OF URINE CAUSED BY A PARALYSIS OF THE BLADDER.

This complaint, to which persons advanced in life are particularly subject, may occur in subjects of any age, in consequence of a violent concussion of the spinal marrow, or (what is very common) if, after having taken a large quantity of drink at a time, a person should neglect to obey the calls of nature, and hold his urine too long. It is also observed to be a symptom of certain typhoid fevers, and consequently, too great attention cannot be paid to the state of the bladder in such disorders. The retention of urine is easily ascertained to exist by the prominence, which it forms above the pubes; a prominence, which may be readily distinguished by its elasticity and circumscription from the general tension of the abdomen, so common in this disease. A retention of urine may either come on in a gradual or sudden manner. In the first sort of case, it begins by a kind of debility, which hinders the patient from completely emptying his bladder, so that, after having made water, he still feels an inclination to repeat the evacuation, and is compelled to make frequent efforts to do so. This inconvenience gradually increases; at length, none of the urine can be discharged; and the bladder rises higher than the pubes, above which part it forms a round circumscribed tumour, the size and elasticity of which are more or less considerable.

In the second kind of case, or that which occurs suddenly, the retention of

the urine is the first symptom, which the patient experiences, and his bladder becomes filled, and distended, in the same manner, as in the preceding case. Most frequently, the swelling, which this viscus forms, is at first not particularly painful, but afterwards becomes very much so. Some patients make frequent efforts to expel their urine; others are more tranquil. This state lasts two or three days, after which the urine begins again to escape from the urethra, sometimes by drops, sometimes in a stream, but, almost always, at the will of the patient. In some instances, as much urine is voided, as the fluid, which is drunk; yet, notwithstanding this, the bladder continues to be distended with urine, and to form an elevation, above the pubes. This circumstance has frequently led practitioners into error, and some of them have even mistaken the swelling of the hypogastric region for an abscess. Collot mentions, that, in his time, this mistake happened very frequently, and that such supposed abscesses would have been often opened, had not the patients warned their medical attendants of the erroneous opinion. M. Sabatier informs us, that he was consulted about a woman, who had been advised to resort to the mineral waters, with a view of dispersing a tumour, which had occurred in consequence of a difficult labour, and which swelling was supposed to be situated in the uterus. The tumour, however, was nothing else, than the bladder, distended with an accumulation of urine, since it disappeared as soon as a catheter was introduced. No suspicion had been entertained of the real nature of the case, in consequence of the patient having voided her urine in a voluntary manner, and reasonable quantity, for five, or six weeks, during which time the swelling had existed.

M. Sabatier makes mention of a case, inserted in a thesis by Dr. Murray, from which it appears, that the swelling of the bladder may become so considerable as to lead to mistakes of a still more serious nature. A delicate woman found her abdomen swell, without any apparent cause, and without experiencing any inconveniences. She imagined that she was pregnant. However, she was soon undeceived by the rapidity, with which her abdomen continued to enlarge, and by the considerable degree of anasarca affecting her lower extremities. The latter affection extended also to the arms, and face. The patient was considered to be dropsical; and a surgeon was sent for to tap her. The fluctuation of a fluid in the abdomen was quite evident. Some diuretics were prescribed, before having recourse to the operation. While such remedies were put to a trial, the patient complained of

having had a total retention of urine for three days; a symptom, which she had not previously suffered. The belly was elastic, and the veins on it were every where swollen. It was judged prudent to introduce a catheter, before employing the trocar. The surprise was very great when eighteen pints of urine were drawn off, and the swelling of the abdomen subsided. The next day, the catheter drew off twelve more pints of urine. The anasarca, which was entirely symptomatic, disappeared. The application of cold water re-established the tone of the bladder, so that, when three pints of urine had been drawn off by means of the catheter, the patient herself could spontaneously expel three or four others, with the aid of some degree of pressure on the hypogastric region. Dr. Murray endeavoured to ascertain, whether the woman got completely well; but, he could not trace this circumstance.

The retention of urine, produced by a paralysis of the bladder, and the swelling, which this viscus occasions above the pubes, may continue for a long while, without patients feeling any other inconvenience, than a sense of weight about the region of the pubes, and the frequent inclinations to make water, which accompany this state. M. Sabatier mentions his having seen patients, who had been attacked by the complaint for more than six months.

The disorder may be relieved by introducing a catheter into the bladder, by which means the urine has an opportunity of escaping. For an account of the manner of introducing this instrument, see *Catheter*.

It is not enough to empty the bladder, care must be taken to prevent the urine from accumulating again, and, consequently, the catheter, according to some, must be left introduced. Others are of opinion, that it is better to pass the instrument whenever the patient has any occasion to make water. According to Desault and Mr. Hey, the bladder regains its contractile power soonest, when the catheter is introduced as often as occasion requires, instead of being allowed to remain continually in the urethra.

When the retention of urine has lasted a considerable time, when the hypogastric region is painful, and the patient is feverish, venesection may be performed, and, in all cases, diluent beverages, of a slightly astringent nature, are to be prescribed. The intestines are to be emptied with glysters, and the regimen is to be regulated by the condition, in which the patient happens to be.

For a certain length of time, things remain in this state. When the urine flows from the catheter in a rapid stream, which

is projected to some distance, and when it also passes out between the catheter and the urethra, it is a sign, that the bladder has regained its power of contraction, and that it can empty itself, without the aid of the instrument. In this circumstance the catheter is to be taken away, and the patient may gradually resume his occupations, and usual mode of life. When the urine only escapes through the catheter, and in a slow stream, the employment of this instrument is always requisite, and its use cannot be discontinued, without hazard of the bladder becoming distended again, and losing whatever degree of tone it may have recovered. However, a catheter cannot be suffered to remain in the bladder more than twelve days, or a fortnight. Some persons have in their urine so much mucus and earthy matter, that an incrustation would not fail to take place on the instrument, if care were not taken, every now and then, to withdraw it and clean it. In other persons, the pressure, which the catheter makes on the part of the urethra, corresponding to the root of the penis, in front of the scrotum, occasions in this situation an inflammation, which ends in mortification, so that a slough about as large as a crown takes place, followed by an opening with loss of substance, which opening remains fistulous during the remainder of the patient's life. The latter inconveniences do not attend the employment of flexible gum catheters.

The time which the bladder takes to regain the power of contracting, varies considerably in different cases. When the disease is accidental and sudden, it frequently goes off in a few days. When it has come on in a slow manner, it usually lasts about six weeks. The cure, however, is not to be despaired of, if the paralytic affection of the bladder should continue much longer. M. Sabatier says, that he has seen patients wear a catheter upwards of ninety days, and yet ultimately get completely well. When there is reason for believing, that the urine will come away of itself, the use of the catheter may be discontinued, great attention being paid to the state of the patient. When he makes water very slowly; when he is obliged to make frequent attempts; and when he feels a sense of weight about the neck of the bladder; this viscus has not recovered the whole of its tone, and the employment of the catheter is still necessary. Sabatier states, that he has often successfully recommended the catheter to be worn only in the night-time, when the patient could make water tolerably well in the day, and experienced the above complaints in the night.

When three or four months elapse, without the urine resuming its ordinary course, Sabatier informs us, that, we may

be sure, that the tone of the bladder is lost for ever. In this unfortunate case, all that can be done is to advise the patient to make continual use of a flexible catheter, which he should be taught to introduce himself, whenever he has occasion. (See *De la Médecine Opératoire par Sabatier, Tom. 2.*)

Among the means deserving of trial, when the contractile power of the bladder does not return with the use of the catheter, I have to mention the tincture of cantharides; blisters applied to the sacrum, and kept open with the savine ointment; and cold washes to the hypogastric region.

2. OF THE RETENTION OF URINE, OCCASIONED BY INFLAMMATION OF THE NECK OF THE BLADDER.

This case makes its attack with the most urgent symptoms. Besides the inclination to make water, and the efforts, which such inclination causes, the patient is affected with a swelling of the bladder above the pubes, a deep-seated pain in that viscus and all the neighbouring parts. Fever, nausea, vomiting, a urinary smell in the breath, and perspiration, great restlessness, a difficulty of breathing, convulsions, and death, are the train of evils, which may ensue.

The present kind of retention of urine demands the employment of the antiphlogistic plan of treatment; particularly, of bleeding, the tinctura ferri muriati, purgative medicines, diluent emollient beverages, opiate glysters, the warm bath and anodynes. This is a sort of case, in which Mr. Henry Earle's proposal of trying the effects of a tobacco clyster might be adopted. Indeed, this is a means, which may be rationally practised in every example, in which a retention of urine obstinately resists ordinary plans of treatment, and is attended with a spasmodic affection of the urethra and neck of the bladder. The three cases, which Mr. Earle has recorded, clearly prove, that tobacco is a remedy, possessing considerable power in such forms of the complaint. (See *Medico-Chir. Trans. Vol. 6, p. 82, &c.*) At the same time, I do not know, that it is more effectual, than opium administered in clysters, which is given in the same description of cases, and, as every body knows, frequently with complete success. The introduction of instruments into the urethra in every instance, attended with inflammation and spasm in that passage, or about the neck of the bladder, ought certainly to be avoided as long as possible, and the trial of antiphlogistic and anodyne remedies made. But, when these are unavailing, the catheter should be resorted to, and its use should never be deferred so long, as to afford any

chance of the distention of the bladder occasioning a paralysis of this viscus. In these cases, it is generally better to use an elastic gum catheter, which is much less irritating to the urethra than a metallic instrument. When the catheter cannot be introduced, and further delay would be attended with a risk of the bladder sloughing, and the urine becoming extravasated, the operation of puncturing the bladder is immediately indicated. (See *Bladder.*)

3. OF THE RETENTION OF URINE, OCCASIONED BY FOREIGN BODIES IN THE BLADDER.

Several kinds of extraneous matter may be lodged in the bladder: for instance, stones, worms, pus, blood, &c. Here, we shall only treat of the retention of urine, originating from the presence of stones, or of blood, because these causes are the most frequent.

One, or more stones in the bladder give rise to particular symptoms explained in the articles, *Urinary Calculi* and *Lithotomy*. They seldom occasion a total retention of urine. If such a case were to present itself, it might be easily understood by preceding circumstances. The complaint might be relieved, and this, perhaps, for a considerable time, by introducing a sound, which would push the stone away from the neck of the bladder, towards the fundus of this viscus. Instances are not uncommon, in which the patients, after having been tormented by the lodgment of stones in the bladder, became afterwards quite free from all kind of uneasiness. Sabatier makes mention of a clergyman, who was sounded by a very skilful surgeon, and who finding himself afterwards free from the pains, which he before suffered, thought, that the surgeon had been mistaken, when he said, that there was a stone in the bladder, and that lithotomy ought to be performed. The patient also bequeathed his body for dissection to the surgical practitioner, in order that the latter might reap instruction from the examination. The surgeon accepted this odd legacy; and, when the body was opened in the presence of numerous spectators, a large stone was found in the bladder.

Blood may descend from the kidneys into the bladder: or it may accumulate in this latter receptacle, in consequence of some injury, or ulceration of its inner coat. When the blood remains in a fluid state, it may be voided almost as easily as the urine itself. But, when it coagulates, the clots, which are formed, may obstruct the neck of the bladder, and occasion a retention of urine; a case which is the more alarming, as the collection of blood generally cannot be drawn off by means of a

catheter. However, one of a very large size should be introduced, in order to try whether the thing is practicable. When this method fails, authors advise a syringe to be fastened on and adapted to the outer end of the catheter, by which means the blood and urine are to be sucked, as it were, out of the bladder. Sabatier states, that this plan has been practised with success, in cases, which seemed almost desperate.

4. OF THE RETENTION OF URINE, CAUSED BY THE PRESSURE OF THE GRAVID UTERUS ON THE BLADDER.

Such pressure often occasions a difficulty of making water, and a retention of urine. Women relieve themselves by leaning down on their knees and elbows, in which position, the uterus makes less pressure on the neck of the bladder. Some introduce one, or two fingers into the vagina, and push the uterus upward. Others must have the catheter introduced, particularly, about the period of parturition. When there are no other impediments to the passage of the catheter, than the cause of the disease, the instrument may easily be introduced.

When, however, the course of the meatus urinarius is rendered crooked, either in consequence of an old prolapsus uteri, or of the pressure occasioned during labour, the urine can only be drawn off by means of a catheter, with a rounded end, which instrument should be first introduced with its handle as much towards the belly as possible, after which, this part of the instrument is to be brought downward by a semi-circular motion. (*Sabatier Médecine Opératoire, Tom. 2, p. B. 7.*)

5. OF THE RETENTION OF URINE CAUSED BY THE ENLARGEMENT OF THE PROSTATE GLAND.

When the swelling of the prostate gland is of an inflammatory kind, the retention of urine makes its appearance by symptoms, which always attend an inflammation of the neck of the bladder. This affection sometimes ends in an abscess, which bursts of itself. Some writers have contemplated the propriety of making an incision into the suppurated gland; but, such a proceeding, perhaps, can never be at all justifiable, or prudent.

Here, exactly the same kind of treatment is proper, which has been recommended for the retention of urine arising from inflammation about the neck of the bladder. In particular, bleeding, the warm bath, opening medicines, anodyne clysters, the tinctura ferri muriati, and, in very obstinate urgent cases, an enema of tobacco,

should be tried. If these means fail, the surgeon may gently endeavour to introduce an elastic gum catheter.

The diseased enlargement of the prostate gland has been treated of in another part of this Dictionary. See *Prostate Gland*. The retention of urine, occasioned by this disease, begins with a difficulty of making water, just such a kind of difficulty, as occurs when the bladder has been deprived of some of its contractile power, and it admits of relief from the use of slightly diuretic beverages. When the complaint becomes more urgent, and the urine cannot be any longer evacuated, the introduction of a catheter becomes indispensable. Although this operation is, in every respect, perfectly easy of accomplishment, it is not always attended with the desired success. The catheter passes in as far as it can; but, the urine is not discharged, because the end of the instrument, according to Sabatier, becomes entangled in the prostate gland, or between a swollen portion of this gland and the neck of the bladder, and does not reach to the situation of the urine. Hence, Sabatier recommends the employment of a catheter with a very long beak. From the account, however, which we have delivered of the alteration produced in the course of the urethra by the morbid enlargement of the prostate gland, (see *Prostate Gland*,) it appears, that the canal in question generally makes, in this case, a sudden turn upwards, just before it approaches the bladder, consequently when a catheter has its end bent a little more upwards, than usual, it is best adapted for passing into the bladder, in the affection under consideration. When the surgeon has succeeded in introducing a catheter, it is to remain introduced, till the bladder has recovered its tone, or contractile power, just as was recommended in the case of paralysis of this viscus. When, however, all efforts to pass a catheter are quite ineffectual, the only remaining resource is to puncture the bladder above the pubes. (See *Bladder, Puncture of*.) In this case, the operation should never be done through the perinæum, or rectum, as the very great size, which the diseased prostate gland sometimes attains, would be an obstacle to making a puncture in either of these situations. Puncturing the bladder, however, is only a temporary means of relief, unless this organ recovers its contractile power, or the surgeon succeeds in introducing a catheter through the urethra. When neither of these circumstances occurs, the cannula of the trocar must not be withdrawn.

The objections, which immediately present themselves to leaving in the cannula, for any considerable time, are: the irritation of the extraneous body; the fear of calculous incrustations forming both on

the outside and inside of the cannula; and the hazard of not being able to find out again the track into the bladder, when the instrument is ever withdrawn. However, Sabatier confirms, that the cannula may sometimes be successfully allowed to remain in the bladder. Collot adduces two instances, in which he found this method very serviceable. Sabatier also refers to another example of similar success, related in a thesis by Murray. An incision had been made above the pubes, in order to be more easily able to introduce the trocar into the bladder. The wound inflamed, suppurated, and was in a healing state; but, as the urine could not be voided through the urethra, the cannula was left in the puncture. Things had gone on in this manner, more than a year, when Dr. Murray saw the patient. The man was sixty years of age, and enjoyed very good health. He was in the habit of taking a stopper out of the cannula, every four hours. The wound had healed very well all round the tube, and was quite free from redness.—(*Sabatier, Médecine Opératoire, Tom. 2. p. 140.*)

6. OF THE RETENTION OF URINE PRODUCED BY STRICTURES IN THE URETHRA.

From the account, which is given of strictures in another part of this Dictionary, (see *Urethra, Strictures of*,) it appears, that almost every stricture, how bad soever it may be, is capable of being rendered still worse, and the morbid part of the urethra, more impervious by a spasmodic affection. Going out of a warm into a cold situation, drinking, and other kinds of intemperance, will often bring on an irritable state of the canal, attended with a spasmodic action of the strictured part, an increased difficulty of voiding the urine, and even a total retention of this fluid. The patient makes repeated efforts to relieve himself; but hardly a drop of urine is discharged. In the mean while, the bladder becomes filled, and ascends above the pubes; the abdomen grows tense and painful; fever comes on; the countenance looks red; the brain becomes affected; and circumstances assume an extremely urgent appearance.

In this case, antiphlogistic means should be adopted, without delay. The patient ought to be bled, if nothing in his constitution and age prohibit this evacuation, which it may even be proper to repeat. He should also be put into the warm bath, and fomentations should be continually applied to the hypogastric region. Slightly diuretic beverages may be prescribed; and leeches put on the perinæum. The principal means, however, from which the greatest benefit may be expected, is a liberal dose of the *tinctura opii*, together

with an anodyne glyster. This is also another example, for which Mr. Earle has particularly recommended the exhibition of tobacco in the form of a clyster, and he has related a case in illustration of the efficacy of the plan. (See *Medico-Chir. Trans. Vol. 6, p. 88.*) The *tinctura ferri muriati*, which according to Mr. Cline, has a specific effect in overcoming spasm of the urethra, seems also worthy of trial. Indeed, it should always be tried before tobacco, which being sometimes violent in its effects, ought perhaps to be the last resource in the way of medicines. When such measures fail in enabling the patient to empty his bladder, and this viscus is becoming more and more distended, an immediate attempt should be made to introduce a small flexible elastic gum-catheter, through the stricture or strictures into the bladder, which object may be frequently accomplished, when due care, perseverance, and gentleness, are not neglected.

Sometimes when a small flexible catheter cannot be introduced, a fine bougie admits of being passed into the bladder, and, on being withdrawn, the urine follows, and is discharged.

When all the preceding plans prove unavailing, and the danger arising from the retention of urine continues to increase, the only remaining resource is to puncture the bladder. The cannula of the trocar should then be left in the wound, till the strictures are either cured, or at least till the urine seems to resume its natural course through the urethra.

Useful information on the subject of retention of urine may be found in *De la Médecine Opératoire, par Sabatier, tom. 2.* *Hey's Practical Observations in Surgery.* *Desault's Parisian Chirurgical Journal.* *Sammeing, Abhandlung über die Schnell und langsam tödtlichen Krankheiten der Harnblase und Harnröhres bey Männern im hohen Alter.* 4to. *Frank. p. 1809.* *Richter's Anfangsgrunde der Wundarzneykunst, B. 6, p. 210, &c.* *Œuvres Chir. de Desault par Bichat, Tom. 3.* *Home's Practical Observations on the Treatment of Strictures, &c. vol. 2. 1803.* Mr. Earle's observations on the efficacy of tobacco are contained in the *Medico Chirurgical Trans. Vol. 6, p. 82, &c.*

UTERUS, INVERSION OF. This case may either be complete, or incomplete. When it is incomplete, only the fundus of the uterus passes through the os tincæ. When the inversion is complete, the uterus becomes entirely turned inside out, passing through the opening in its cervix, dragging along with it a part of the vagina, and descending more or less far down, sometimes even between the patient's thighs.

The inversion of the uterus mostly arises from the manner in which the placenta is

extracted after delivery. Just after parturition, the parietes of the uterus have not had time to become contracted, and the mouth of this viscus is as capacious as it can possibly be. It is easy of comprehension, how it may happen, that, when things are thus disposed, the uterus may follow the after-birth, which is attached to the parietes of this organ, and thus become inverted. The event is particularly liable to happen; 1st, When a premature attempt is made to extract the placenta. 2dly, When the funis is pulled outward, without any care being taken to support the uterus by the fingers of the left hand. 3dly, When the operator draws the after-birth outward in too rough and forcible a manner. It is true, that the placenta is sometimes so adherent, that its extraction is very difficult, and some risk must be encountered of dragging down the uterus with it. However, this unpleasant occurrence may generally be avoided by taking care to separate the placenta, by introducing one's fingers into the cavity of the uterus.

The inversion of the uterus, following parturition, should not always be ascribed to unskilfulness on the part of the practitioner. The accident frequently happens, notwithstanding every precaution to prevent it, either because the patients make too violent efforts to deliver themselves; or because the uterus is enlarged and heavy; or else in consequence of some natural disposition in the uterus, which disposition can neither be foreseen nor prevented. Ruysch has seen an inversion of the uterus take place, after the expulsion of the placenta, although the delivery had occurred in the most favourable way. This disposition is very common in persons, who have once been afflicted with an inversion of the uterus. Amand makes mention of a woman, who had had an inversion of the uterus in her first delivery, and had been freed from the affliction by this practitioner. The same patient was attended by Amand again in her next accouchement, and another inversion of the uterus, quite as bad as the first, would certainly have happened, had not Amand, on perceiving the disposition to the accident, introduced his finger into the cavity of the uterus, and separated the placenta from its attachments, before making any attempt to extract it.

Besides the causes of the inverted uterus, which are connected with parturition, there are some others, which have no concern with it whatsoever. Ruysch, Mauriceau, and Lamotte, were of opinion, that the inversion of the uterus could only happen at the time, when the placenta was extracted, or a little while afterwards. The occurrence seemed to them quite impossible at any other period, both because

the substance of the uterus is very thick and solid, and its mouth is very contracted. However, Sabatier remarks, that there are many facts, which prove that this disease may depend on internal causes, and that it may affect women, who have had no children, as well as others, who have had them. Polypi of the uterus are causes of this kind. As their pedicle is attached to the fundus of the uterus, and is very firmly inserted into it, they may easily drag it downward, when its texture is lax and soft, particularly, as their action, arising from their weight, is continual and uniform. We may also reckon among the causes, the hemorrhages, to which women are subject, both because they relax the texture of the uterus, and because they are usually attended with an acute pain, which makes the diaphragm and abdominal muscles contract, and act upon the uterus with all their power.

When an inversion of the uterus takes place after delivery, there are certain symptoms by which it may easily be known. The uterus, when in its natural situation, presents itself in the hypogastric region in the form of a round circumscribed tumour; but, when it has fallen downward, and become inverted, the above tumour cannot be found, and, a vacancy may be felt in the situation, which it ought to occupy. When the inversion is incomplete, an examination with the fingers detects in the vagina a tumour, shaped like the segment of a sphere, having a smooth surface, and being surrounded with the cervix uteri, as with a kind of collar, round which the finger may easily be passed, either between the kind of collar and the uterus, or between the collar and the vagina. When the inversion of the uterus is complete, there is in the vagina, and sometimes quite protruded, a tumour, apt to bleed, of an irregularly round shape, with a smooth surface, and hanging by a neck, which is surrounded by the above circular, thick, fleshy, substance, consisting of the os uteri itself. In the incomplete inversion, patients feel acute pain in the groins, and kidneys, an oppressive sense of heaviness in the hypogastric region, and a tenesmus, which, compelling them to make violent efforts, forces the uterus down more and more, and produces a total inversion of it. To such symptoms are often added hemorrhages, which are more or less copious. But, when the inversion is complete, the pain is more acute, the loss of blood more considerable, and the patient is often affected with peculiar weakness, which is frequently followed by cold sweats, convulsions, and delirium.

The reduction of the uterus is the only method, by which the above described sufferings can be appeased, and it ought to be put in practice the more quickly, in

proportion to the urgency of the symptoms. When these are pressing, the least delay may be followed by the worst consequences. Some women, indeed, perish in a few hours, and, when they live longer, the reduction becomes exceedingly difficult, because the uterus and its cervix are continually becoming more and more contracted.

Sabatier censures the advice to put some linen between the hands and the uterus, in making the reduction, as an unnecessary measure, and one, which bereaves the operator of the information to be derived from the organ of touch, relative to the progress of the operation. The manner of proceeding can hardly be determined by any precepts. It must be regulated by existing circumstances; and the trial should not be abandoned as long as the patient's strength will allow a perseverance. Perhaps, however, if the tumour should be in an inflamed state, it might be prudent, before attempting to reduce it, to take away blood, put the patient in the warm bath, use emollient applications, exhibit anodyne medicines, &c.

When the inversion of the uterus is complete, and the reduction has not been accomplished in due time, an endeavour must be made to quiet the spasms and pain arising from the accident, and the surgeon must await what nature will do for the patient. Many die; while others survive, subject to an oppressive sense of weight, and frequent hemorrhages, which bring on great emaciation. Sabatier informs us of his having seen two patients, who had had an inversion of the uterus, during six months, and who were still able to go about their family affairs. The same author says, he has heard of some other persons, who have had an inversion of the uterus several years.

One of the most afflicting consequences, which may result from an inversion of the uterus, is so considerable an inflammation of the part, as to induce a danger of its mortifying. In this circumstance, some have proposed to extirpate the uterus; an operation, however, that has not been attended with any degree of success, as the majority of patients on whom it has been practised have died. However, there are instances recorded of women having recovered after such an operation. Vieussens has related a case of this kind, in which a ligature was applied round the neck of the swelling, and the part below amputated.

The practice of extirpating the inverted uterus, through apprehension of the part mortifying, however, cannot be reprobated in terms too strong. The only alleged reason for having recourse to the operation, is the very considerable degree of inflammatory swelling, which affects the

part. But, it is not altogether impracticable to bring the uterus into a state again, in which the inconveniences, arising from its inversion, would be very supportable, so that an operation might be avoided, which is always attended with extreme danger. Even supposing mortification were to take place, the indication would be to appease the bad symptoms, and promote the separation of the sloughs by suitable applications. Rousset has recorded an example, in which the latter mode of practice was adopted with success.

Some writers have not been content with advising the extirpation of the uterus, when it is entirely inverted, very painful, and irreducible, in consequence of the contracted state of the cervix of this organ; but, they have also thought such a proceeding proper in cases of a complete prolapsus, when the part is much swollen and inflamed. Instances have been adduced, illustrative of the success of this operation. However, it is now generally thought, that most of these examples are invalid, as polypi, growing from the uterus, frequently attain so considerable a size, that they protrude out of the vagina, so as to have occasionally been mistaken for the uterus itself. These have been extirpated with a ligature, with most beneficial consequences to the patient.

There is no doubt, however, that, in a few instances, the uterus has been amputated, and the patient has recovered.

Although it is easy to distinguish the inversion of the uterus, which happens soon after delivery, it is not so to make out the nature of such cases, as happen in other circumstances, notwithstanding the presence of the same kind of symptoms. As cases of the latter kind are exceedingly uncommon, and, consequently, they are not at all expected, mistakes are the more liable to be made. A very little attention suffices for discriminating an inversion of the uterus from a polypus, with which it has sometimes been confounded. In short, the pedicle of a polypus is always narrow; the tumour is not very sensible, and is irreducible; whereas the uterus forms a semi-spherical swelling, sometimes a little oblong, but, always broader above, than below. It is very sensible, and may be easily reduced.

The reduction of the inverted uterus is also the only step, which can be taken, whether the accident has arisen from the weight of a polypus, or from hemorrhages. However, this proceeding is generally useless, when the disease originates from obesity. In the latter case, as the cause still continues in full force, it in general soon displaces the uterus in the same way, as before, and a pessary is the only means, to which the patient can resort. This in-

strument is to be worn, rather with a view of supporting the weight of the abdominal viscera, which pushes the uterus down into the vagina, as well as the fundus, through the cervix of the womb, than with any design of preventing the inversion. (*Sabatier, Médecine Opératoire, tom. 2.*)

UTERUS, POLYPI OF. See *Polypus*.

UTERUS, PROLAPSUS OF. This may take place in three different degrees. When the prolapsus occurs only in its first or second degree, the uterus is situated in the vagina, where a pyriform tumour may be felt, round which it is easy to pass the end of the finger. At the lower part of this tumour, an opening, placed transversely, may also be distinguished. In the first, or slightest degree, the uterus is situated higher up, than in the second. When the disease has proceeded to the third, or last degree, the uterus is completely protruded out of the vulva. In the latter circumstance, it always drags down the vagina, which becomes doubled on itself, and it also draws down a part of the bladder, which is connected with the upper part of the latter tube. It also sometimes happens, that some of the abdominal viscera insinuate themselves into the kind of cul-de-sac, formed by the vagina, and they then considerably increase the size of the tumour. The swelling, occasioned by a complete prolapsus of the uterus, is of an oblong, nearly cylindrical form, and it terminates below in a narrow extremity, in which a transverse opening, the *os tincæ*, may be discerned, from which the menses are discharged at the periods prescribed by nature. The cylindrical shape of the tumour is the more apt to lead to mistakes, as the vagina, being doubled on itself, and exposed to the effects of the air, sometimes assumes an appearance very similar to that of the skin. Hence, women, afflicted with a complete prolapsus uteri, have sometimes been regarded as hermaphrodites, in consequence of the tumour having been mistaken for a penis. Saviard has recorded an instance, in which this kind of error was made.

The inconveniences, arising from the first and second degrees of prolapsus uteri, are a sense of heaviness in the pelvis, and a degree of uneasiness in the kidneys. These complaints are aggravated, when the patient sits up or walks about. On the contrary, they diminish, and even entirely subside, when the patient has remained a certain time in bed.

The symptoms, attending a complete prolapsus uteri, are of a more severe nature. The patient experiences a greater sense of heaviness in the pelvis, and pain and dragging in the loins. She is troubled with tenesmus, and sometimes feels acute pain in the tumour itself, which is subject to inflame, and ulcerate, in con-

sequence of its depending posture, the friction, to which it is exposed, and the irritation of the urine, as this fluid runs over it.

The uterus, when only affected with the first or second degree of prolapsus, may be easily reduced. Indeed, it often resumes its natural situation, when the patient is put in a position, in which she lies on her back, with her loins raised a little higher than her chest. When this method is insufficient, the fingers may be introduced into the vagina, for the purpose of accomplishing the reduction. The patient suffers no pain, at the time when the reduction is performed, which, for the most part, takes place spontaneously. By the latter circumstance, a prolapsus uteri may be discriminated from polypi, either of the uterus, or vagina, which tumours do not admit of being reduced, which are in shape, broader below, than above, and which present no aperture, similar to the *os tincæ*.

When the uterus is affected with a complete prolapsus, the reduction is not so easy of accomplishment. The great number of parts, which the displaced viscus drags downward with it, and the tumefaction, which sometimes follows, render it necessary to take some preparatory measures, before trying to replace the part in its natural situation. For this purpose, the patient should be kept in bed, be put on a low regimen, be bled, take purgative medicines, use the warm bath, and drink diluent beverages, while emollient applications are to be made to the part itself. This plan of treatment has often been attended with complete success, in cases of prolapsus uteri, of long standing and considerable size. Ruysch was against making any attempt to reduce the uterus, while this part was inflamed and swollen. He also thought, that the operation should be postponed when the uterus was in an ulcerated state. However, Sabatier observes, that, as this complication is only an accidental one, and merely arises from the friction, to which the tumour is exposed, and the irritation of the urine, the plan of immediately replacing the part cannot be attended with any danger. On the contrary, since the cause which produces and keeps up the ulceration will cease, as soon as the reduction is accomplished, it follows, that the sores will soon heal after the uterus is put into its natural situation again.

When we reflect on the position of the uterus, on the strength of the ligaments, destined to support it, and on the manner in which the vagina is connected with the surrounding parts, we cannot easily conceive, how the womb can become so much displaced, as it is in cases of complete prolapsus. It is still more difficult to com-

prehend, how the uterus can become displaced during pregnancy, even when this viscus has attained its utmost state of distention. However, this sort of case has frequently happened. Sabatier remarks, that he could adduce several examples, and quotes an instance from the *Traité des Accouchemens de Portal*.

The prolapsus uteri, which occurs during pregnancy, demands the utmost care. The part is capable of being reduced, while the patient is in the early stage of pregnancy. When pregnancy has far advanced, or the disease is of long standing, the reduction is difficult. Perhaps, says Sabatier, it may be more prudent in these circumstances, to let the uterus continue protruded, than to disturb the mother and foetus with reiterated attempts to reduce the part. The uterus, however, should not be left to itself; but be well supported with a suitable bandage, and the patient ought to be kept in her bed. When the prolapsus uteri occurs at the very period of delivery, every attempt at reduction is both useless and dangerous. In this case every exertion should be made to promote the delivery of the foetus, by gradually dilating the os tincæ, which should, at the same time, be carefully supported. The extraction of the placenta also requires a great deal of caution, and it should be accomplished by introducing a hand into the uterus, with the palm turned away from the cavity of this viscus, towards the outside of the placenta, which is to be gradually separated by proceeding from one of its edges towards its centre.

In cases of complete prolapsus uteri, Ruysch was an advocate for leaving the expulsion of the foetus, if alive, to be effected by nature; and the same writer advises us to be content with supporting the os tincæ. But, when the child is dead, he recommends extracting it with one hand, while the uterus is supported with the other. Sabatier, however, entertains different sentiments. The expulsion of the child is not less the effect of the contraction of the diaphragm and abdominal muscles, than of the womb itself. Hence, it is easy to conclude, that when either of these agents fails in co-operating, the delivery becomes either very difficult, or impossible. This is exactly what happens in the present case; for the uterus having fallen down, can no longer be compressed by the action of the diaphragm and abdominal muscles. Sabatier sets down the practice, advised by Ruysch, as an exceedingly dangerous one; because, the efforts, made by the mother to deliver herself, would have a tendency to render the prolapsus uteri more complete, and thus increase the dragging of all those parts, with which this organ is connected. Sabatier, also, can-

not discern the reason why Ruysch should recommend the line of conduct to differ, according to the different state of the child. This is, probably, quite passive in parturition, and contributes not in the least to its own expulsion. Sabatier, therefore, contends, that the treatment should not be at all influenced by the consideration of the child being dead or alive.

In whatever degree a prolapsus uteri has taken place, it is not sufficient to have reduced the part. The prolapsus would soon recur, if it were not prevented by the employment of astringent injections and pessaries.

UTERUS, RETROVERSION OF.

A retroversion of the uterus is said to happen, when the fundus of this viscus, carried by its own weight, and forced downward by the action of the diaphragm and abdominal muscles, becomes situated between the sacrum and posterior part of the vagina, while the cervix uteri becomes inclined towards the symphysis pubis. This kind of case was not understood till about the middle of the preceding century. Sabatier states, that Gregoire, a member of the college of surgery at Paris, first mentioned it in his private instructions in midwifery. Walter Wall, an English surgeon, who had attended Gregoire, suspected, that he had met with a retroversio uteri in a woman, some months advanced in pregnancy, and he called in Dr. Hunter, in order to have the advantage of his advice. The woman was attacked with an obstinate constipation, and retention of urine, and died in about a week. A large tumour was found occupying the whole of the pelvis, and pushing the vagina against the os pubis. It had been found impracticable to push the swelling back into the abdomen, although the patient had been put on her knees and elbows, while one hand had been introduced into the vagina, and two fingers of the other hand into the rectum. Some curiosity was entertained, concerning what state things would be found in. Opening the body shewed, that the bladder, which was exceedingly full of urine, occupied almost the whole anterior part of the abdomen, in the same manner as the uterus does in the last month of pregnancy. When the bladder had been emptied, that part of it, in which the ureters terminate, and which is connected with the vagina and cervix uteri, was found raised up, as high as the upper aperture of the pelvis, by a large tumour, which filled the whole cavity of the pelvis, and was found to be the uterus. A catheter, when passed into the vagina, could be made to lift up the latter viscus, and the upper part of the tumour. This portion of the swelling, on which the bladder lay, consisted of

the cervix uteri while the fundus of this organ was situated downwards towards the os coccygis and anus. The uterus had attained such a magnitude, that it could not be taken out of the pelvis, before the symphysis pubis was divided, and the two ossa innominata were pulled asunder. It was found impossible to assign any cause for the manner, in which the uterus had become displaced, as the patient had been making no exertion, had met with no fall, and had only been frightened at something just before the complaint commenced.

Dr. Hunter, struck with the singular nature of the case, thought it deserving of attention among medical men, and he made it the subject of a lecture, which he delivered to his pupils in 1754. He was afterwards consulted by several persons, who were afflicted with the retroversio uteri; but, not in so acute a way, as in the above instance. All the patients were in the third month of pregnancy, and first suffered a difficulty of making water, succeeded by a retention of urine, and afterwards by constipation. Dr. Hunter always emptied the bladder by means of a catheter and glysters, which measures sometimes effected a cure, the uterus spontaneously resuming its natural position. In every instance, the accident disappeared, when pregnancy was more advanced, and the uterus had acquired larger dimensions. Success was not always obtained; for, in some cases, in which Dr. Hunter was consulted too late, the trials to replace the uterus proved fruitless, and the women died. Dr. Hunter was so firmly convinced of the impossibility of saving patients, circumstanced in the above manner, unless extraordinary means were resorted to, that he thought one should endeavour to diminish the size of the uterus, by introducing a trocar into the body of this viscus, through the posterior parietes of the vagina, so as to let out the water of the amnios, the relative quantity of which is known to be greater, in the early, than in the advanced, stage of pregnancy.

Such a puncture might certainly be the means of the uterus resuming its natural position; but, there would be considerable danger of its exciting the contraction of the uterus, and causing abortion. No risk of this kind would be encountered by puncturing the bladder above the pubes. In this manner, a free passage would be afforded for the escape of the urine, and the reduction of the uterus might be effected.

Mr. Lynn, a surgeon in Suffolk, has seen the bladder burst, and the urine become extravasated in the abdomen, in a case of a retroversion of the uterus, in consequence of the patient's refusal to submit

to the preceding operation. The woman was forty years of age, of a relaxed habit, mother of several children, and had been pregnant four months. She had been for some time before afflicted with a prolapsus of the vagina. The swelling had been a few days reduced, when, in consequence of tripping, she felt something become displaced in her abdomen, and fall towards the lower part of her back. She was immediately attacked with constipation, retention of urine, nausea, and pain in her belly. The means, which were employed, not proving effectual, Mr. Lynn suspected, that a retroversio uteri had happened, and introduced his fingers into the vagina, in order to ascertain the fact. His fingers were stopped by a tumour, as large as a child's head. The swelling occupied the back part of this passage, and descended as low as the perinæum. Being certain, that the uterus was displaced, he attempted to reduce it. The patient was put into various positions, and the fingers of one hand were introduced into the vagina, while those of the other were passed into the rectum. The use of the catheter was not forgotten; but, it could not be introduced far enough to reach the urine. Glysters were stopped at the very beginning of the rectum. The abdomen was exceedingly tense, especially, in the hypogastric region. A proposal was made to puncture the bladder; but, the patient refused to submit, and preferred being left to her fate. On the seventh day of her illness, she was very much reduced; and became affected with nausea, and hiccough, the forerunners of the mortification, which was about to happen. At length, she felt something give way in her abdomen, and, the ease, which succeeded, revived her hopes. These, however, were not of long duration; for, after being delivered of the fœtus, she sunk and died the next morning. On opening the body, the bladder was found to have sloughed and burst at several points, and two pints of urine were consequently extravasated in the abdomen.

We may conclude, from what has been stated, that the retroversio uteri is an exceedingly dangerous affection. However, it is not invariably fatal, particularly when the patient receives succour, before the disorder has made much progress. It only occurs in the early months of pregnancy, and in women, whose pelvis is very wide, while its brim is very contracted. If the uterus, which occupies a pelvis of this conformation, should be pushed back by a distended state of the bladder, and pressed against the sacrum, while the soft parts yield, the viscus, in question, becomes, as it were, wedged, and is incapable of changing its position. In this immoveable state, it presses upon the sur-

rounding parts, and these upon it, so that a very serious train of bad symptoms are the consequence.

The first care of a practitioner, consulted in a case of retroversio uteri, should be to empty the bladder and large intestines, and to relax the parts by every possible means. Then, he should immediately proceed to replace the uterus, by placing the patient in a suitable posture, and making methodical pressure in the rectum and vagina. Should he be so fortunate as to succeed, the patient is to be confined in bed, her bowels are to be kept open, and she is to be advised always to obey the calls of nature the first moment she feels any inclination to make water. She is also to be enjoined to avoid all kinds of exertion, and wait, till the gradual enlargement of the uterus removes the possibility of this viscus descending into the pelvis. (*Sabatier, Médecine Opératoire, Tom. 2.*)

UVA URSI. The author of the *Pharmacopœia Chir.* remarks, that this plant, which was first brought into notice by De Haen, has been generally considered as a powerful remedy in calculus; but that it has not been proved, in any instance, to possess the properties of a solvent. The late Dr. Austin, however, recommended it upon the principle of its lessening the irritability of the bladder, and diminishing that secretion of diseased mucus, which, he supposed, greatly contributed to the augmentation of the stone.

Mr. Bell, of Edinburgh, strongly recommends it in that state of a gonorrhœa where the irritability of the bladder is excited in a high degree, and where the urine is loaded with viscid matter. In these cases, he directs the powder to be given in doses of a scruple or half a dram, three times a day. A remedy of this sort is certainly a great desideratum in surgery.

Dr. Saunders directs three drams of uva ursi to be macerated in a pint of hot water, and two or three ounces of the strained liquor to be given three times a day. (*Pharm. Chirurg.*)

UVULA, AMPUTATION OF. The uvula is subject to several kinds of enlargement, in which it becomes longer and more bulky, than natural, or in which it merely has its length increased. In consequence of such changes, it acts as an impediment to swallowing, and speaking, or else causes a disagreeable tickling at the root of the tongue, with which it comes into contact, and thus it may excite frequent retchings, and an annoying cough.

When things have attained this state, medicines are often ineffectual, and the only plan of relief consists in amputating a portion of the uvula, a very simple ope-

ration; which has been advised to be done in various ways.

The ancients recommended taking hold of the uvula with a pair of forceps, and cutting off the piece below the blades of the instrument. Celsus remarks: *Neque quidquam commodius est quàm uvella apprehendere, sub eaque, quod volumus, excindere.* Fabricius ab Aquapendente objects to this method of operating, on the ground, that it is necessary to employ both hands, so that there is a necessity for the aid of a third for holding the tongue and lower jaw. He prefers employing scissors, and leaving the left hand at liberty. When the uvula had been cut off, he advised a heated spoon to be applied to the cut end of the part, with a view of stopping the bleeding.

Paré speaks in favour of the method, preferred by Celsus. When the size of the uvula is considerable, and there is reason to fear, that the vessels will bleed freely, he recommends the application of a ligature to the part, by means of an instrument, composed of a ring, mounted on a slender handle, and formed with a groove upon its convexity. A ligature is put round the ring with a slip-knot, which is to be tightened by means of another ring, of much smaller size, mounted, like the preceding one, upon a long slender handle. The ligature is to be left in the mouth, and, when it does not seem to make sufficient constriction, it is to be tightened.

Fabricius Hildanus has subsequently described an instrument, constructed on the same principles, and applicable to the same purposes. Scultetus made use of the latter on a soldier, whose uvula was affected with the venereal disease. This author does not state, however, whether the ligature, which was applied in this way, was painful, productive of considerable inflammation, or whether the patient suffered much inconvenience from the presence of the ligature. Such effects were probably produced.

Heister, in plate 21, has given an engraving of an instrument, which was invented by a Norwegian peasant, in whose country a relaxed state of the uvula is said to be a very common affection. The contrivance was perfected by Raw. It is only necessary for me to state, that it is a kind of knife, concealed in a sheath. At the end of this last part, when the blade is drawn back, a notch is left, in which the uvula is to be engaged, and then divided by pushing the knife forwards.

Sabatier's plan of cutting off a portion of the uvula, bears a considerable resemblance to the method described by Celsus. After having placed the patient on a high chair, and in a good light, with his head properly supported, Sabatier

takes hold of the uvula with a pair of forceps, made with holes in the blades, like those used for the extraction of polypi from the nose. He then divides the uvula with a pair of scissors, made with concave cutting edges, like the scissors recommended by Levret for dividing the umbilical cord. As the uvula is rendered tense with the forceps, perhaps, any other kind of scissors would answer equally well; but, Sabatier states, that those, which he uses, have the advantages of taking hold of a larger piece of the uvula, and of not letting it slip away.

The perforated forceps also take hold of the part better than common ones do, from which it is apt to slip. Sabatier observes, that he has never seen any bleeding of consequence follow this trivial operation. (See *Médecine Opératoire*, Tom. 3.)

In the *First Lines of the Practice of Surgery* will be found an engraving of a pair of scissors, which seem well calculated for cutting off portions of the uvula, as they have at the end of one of their blades a transverse piece, which prevents the part, about to be cut, from slipping away.

V.

VAGINA IMPERFORATE. It is very common to meet with female infants, born with different kinds of imperforations of the vagina. Sometimes, this passage is not completely shut up, so that the usual evacuations happen in an uninterrupted manner, and it is a considerable time before the malformation is discovered. Doubtless, there has often been occasion to obviate the defect in question, in order to qualify young women for marriage. Some females have certainly become pregnant, notwithstanding the sort of obstruction alluded to, and, in these cases, the membrane, which shuts up a part of the mouth of the vagina, has either been torn by the effects of labour, or been divided as much as was necessary for promoting this process of nature.

What is more curious, is, that there should have been found two membranes, one placed beyond the other, and obstructing the vagina. That, which is commonly met with, is nothing more than the hymen, which is thicker, and stronger, than natural. Ruysch relates, that a woman, who had been in labour three days, could not be delivered. The head presented itself; but, was prevented from coming out by the hymen, which shut up the vagina, and was very tense. Ruysch made an incision into the membrane; but, to no purpose, since there was another membrane, of a thicker texture, and situated more deeply in the passage, hindering the delivery of the child. On an incision being made into this second membrane, the child was expelled, and the case ended well.

When the vagina is completely imperforate, as soon as the time of the menses commences, a great many complaints occur, which afflict the patient with more

severity, in proportion as the blood accumulates in the passage, and they may even lead to a fatal termination, when the cause is not understood, or not detected till it is too late. The complaints alluded to, are very similar to those of pregnancy; for instance, rumbling noises in the bowels, loss of appetite, nausea, vomiting, enlargement of the mammae, spasms, convulsions, swelling of the abdomen, &c. Hence, girls, in this situation, have often been supposed to be pregnant, although they were not in a state even to become so; and some young women have been known to die, after suffering the most afflicting symptoms.

When the only malformation consists in the orifice of the vagina being shut up by a membrane, the patient may be easily relieved by a crucial incision, or a single cut, the edges of which are kept apart by a tent of suitable shape and size. Instances of the success of such an operation are to be found in numerous writers. Fabricius ab Aquapendente informs us, that a female child was born with a membrane, which completely shut up the vagina. The girl experienced no inconvenience from it, till she was about thirteen years of age, when the period of her menses began. As the blood was retained, she became afflicted with more severe pains in the loins, the lower part of the abdomen, and about the upper part of the thighs. It was supposed, that she was attacked by the sciatic gout, and she was treated accordingly. Notwithstanding the medicines, which were prescribed, she became hectic, and reduced to a complete state of marasmus, in which she passed restless nights, lost her appetite, and was delirious. A painful, very elastic tumour afterwards took place in that part of the

abdomen corresponding to the uterus. The pains were aggravated every month at the period, when the patient ought to have menstruated. She was in a dying condition, when Fabricius ab Aquapendente was consulted, who, after ascertaining the real nature of the case, performed the requisite operation. A prodigious quantity of black putrid blood was discharged from the vagina; the bad symptoms gradually subsided, and the patient recovered.

It is not always equally easy to cure the imperforate vagina, when the malformation is produced by an extensive accretion of the sides of this passage to each other. The success of the operation is more doubtful, because, it is impossible to reach the situation of the blood without cutting through a considerable thickness of parts, in doing which there is some danger of wounding the rectum, or bladder. A lady, twenty-four years of age, after having tried, for eight years, such remedies as seemed best calculated for exciting the menstrual discharge, became affected with a large hard swelling of the abdomen, and a kind of herpetic affection round the body near the navel. At length, it was discovered, that the imperforation of the vagina was the sole cause of all the bad symptoms, which the patient had long endured. An incision was made, which enabled the operator to introduce his finger into a large cavity, and which gave vent to a considerable quantity of blood. It was thought, that an opening had been made into the vagina; but, the patient having died three days afterwards, it was seen, that a mistake had been made, as the cavity, in which the finger had been introduced, was that of the bladder. The vagina was closed below by a substance an inch in diameter, and half an inch thick. The upper part of this passage, the uterus, and the Fallopian tubes, were exceedingly enlarged, and filled with a dark-brown, sanious fluid. A similar fluid was found extravasated in the abdomen, and, it was discovered to have got there through a rupture, which had taken place in the Fallopian tube. The ovaries were in a natural state. De Haen, who has related this case in the sixth part of his work, intitled *Ratio Medendi*, was of opinion, that, in order to avoid opening the rectum, or bladder, only one oblique cut should be made in the membrane, which stops up the vagina, just as was advised, by Méeckren. (*Sabatier de la Médecine Opératoire*, Tom. 1.)

VAGINA, PROLAPSUS, OR INVERSION OF. According to Sabatier and Levret, the prolapsed part does not consist of all the coats of the vagina, in the same manner as the inverted uterus is formed of the

whole substance of that viscus. These writers contend, that the lining of the vagina is alone displaced, in consequence of the swelling, and thickening, with which it is affected. Richter, however, does not accede to the opinion of Sabatier and Levret upon this point; but, describes the vagina as being liable to two kinds of prolapsus. In one case, all its tunics are stated to be included in the protrusion, the part becoming inverted at the same time that it falls down. In the other example, it is only the relaxed lining of the vagina, which descends, and makes a protrusion.

The possibility of a prolapsus of the whole of the vagina, together with all its coats, says Richter, has been doubted by Sabatier and Levret; but, without any real foundation. If it be possible for the inner coat of the vagina to separate from the external, with which it is intimately connected, (an event, which every body admits as happening in the second kind of prolapsus of the vagina,) why, asks Richter, should it be impossible for the whole of this tube, together with all its coats, to be separated from the surrounding parts, to which it is less closely adherent? Sometimes, the rectum, inclusive of all its coats, forms what is termed a *prolapsus ani*, and why may not the vagina be displaced in a similar manner, since it must be much more liable than the rectum to be propelled downwards in the violent straining at the time of delivery? Richter asks, whether every prolapsus uteri is not accompanied with such a displacement of the vagina? Cases are upon record, where the prolapsus of the vagina happened all on a sudden, in consequence of falls, the starting of a horse, &c. (*Hoin, Levret, Journal de Médecine*, Tom. 40.) Here it cannot be supposed, that the case was merely a protrusion of the inner coat, which can only be gradually relaxed and elongated. Lastly, some instances, in which the prolapsus of the vagina was several inches in length, have been gradually reduced by means of external pressure. (*Hoin*.) How can we imagine, says Richter, that such cases could proceed from any degree of relaxation, to which the membranous lining of the vagina is liable?

Richter acknowledges, however, that a prolapsus of all the coats of the vagina is much less common, than that arising from relaxation of the membranous lining of this passage; he states, that when it occurs, it is generally as a consequence of a prolapsus of the uterus; and that it cannot easily happen at all, except about the period of delivery. (See *Anfangsgr. der Wundarzneylkunst*; B. 7, *Vierte Kapitel*.)

According to Sabatier, the prolapsus, or inversion, of the vagina appears like a

thick, circular substance, irregularly pleated in the middle, and at the bottom of which the cervix uteri is situated, having descended further down, than natural. The prolapsed portion of the vagina increases, or diminishes, according as the patient sits up, or keeps in bed a certain time. The complaint is accompanied with a sense of heaviness in the hypogastric region; tenesmus; and a difficulty of making water, in consequence of the alteration produced in the direction of the meatus urinarius.

Such is the prolapsus of the vagina in an early state; but, when it has been of long standing, and the patients have remained, for a long while, without any assistance, the membranous lining of the passage becomes more and more thickened; the tumour, which it forms, becomes more considerable, elongated, and hardened. In this state, there still continues at the lower part of the swelling, an opening, out of which the usual evacuations are made. The grievances, which patients suffer, are similar to those arising from a prolapsus uteri, to which, indeed, the present case bears a great resemblance. The prolapsus vaginæ, however, differs, inasmuch as the tumour, formed by a descent of the uterus is very firm, and terminates in a narrow end, on which may be observed the longish transverse opening, named the os tinæ, while the tumour, arising from a prolapsus of the vagina, is soft, thicker below, than elsewhere, and ends in an irregular aperture.

Occasionally, a prolapsus of a very limited portion of the vagina is observed. This case is generally the consequence of an uncommon sort of rupture, termed the *vaginal hernia*, (See *Hernia*); but, it should also be known, that, in some cases of dropsy, a circumscribed protrusion of the vagina, in the form of a cyst, or pouch, filled with fluid, is sometimes noticed. (*Richter, Op. et loco citato.*)

When the prolapsus vaginæ is recent, the part may be easily reduced, and kept up with a pessary. The use of astringent lotions will also tend to prevent a relapse. But, when the case has been of long standing, it is neither easy to effect the reduction, nor to prevent a recurrence of the disorder. Softening, relaxing remedies, in this circumstance, are recommended, and the patient should, in particular, confine herself to her bed, and wear a T bandage, which should be made to press upon and support a piece of sponge in the orifice of the vagina.

It is reasonable to expect, that after a prolapsus vagina has continued a long while, the reduction must be difficult; because, the vagina in this state becomes affected with swelling and induration. According to the reports of Hoin and Levret, a large protrusion of this kind, ten inches

in length, was so diminished by keeping the patient invariably confined in bed upon her back, that, in the course of a month, the rest of the tumour admitted of being reduced. Indeed, as Richter observes, there can be little doubt, that the treatment, which has been advised by some authors, for the diminution of very old, enormous, omental ruptures, would here be equally applicable; viz. long confinement in bed upon the back, with the buttocks somewhat elevated; unremitting, well directed external pressure; a very low diet; and repeated mercurial purges. By such means, Richter thinks, that the swelling might be in many instances sufficiently lessened to admit of reduction.

During pregnancy, a prolapsus of the whole substance of the vagina may cause much embarrassment and even danger. In one case of this description, where the protrusion was five inches in length, it became necessary to turn the child, and the displaced vagina was lacerated. The woman, however, recovered. (*Pietsch, Journal de Médecine, Tom. 34.*) In another instance, where the prolapsus became, at each return of the labour-pains, as large as a man's head, the practitioner succeeded in holding the parts back, while delivery was effected with the aid of the forceps. (See *Loder's Journal, 1 B. p. 490.*) When this is impracticable, it is necessary, according to Richter, to make an incision through both sides of the prolapsus; a measure, says he, to which the practitioner may the more readily make up his mind, inasmuch as the parts have, in some cases, been lacerated, without any ill consequences.

A prolapsus of the inner membrane of the vagina, while small and recent, may perhaps be removed by astringent applications. When, however, it is of long standing, indurated, and of large size, much expectation of success from this treatment cannot be entertained. Richter sees no reason why, in such a case, the superfluous relaxed part should not be cut away, especially, when the disease is accompanied with ulceration, and other serious complaints. As he observes, there can be no doubt, that a prolapsus of the inner membrane of the vagina, when limited to one part of this canal, may always be safely extirpated, either with a knife, or a ligature. (*Anfangsgr. der Wundarzn. B. 7, Chap. 4.*)

As the swelling of the membranous lining of this passage is folded back on itself, it sometimes increases in such a degree, that the tumour, thus occasioned, falls into a state of mortification. In this event, some writers have advised the extirpation of the swelling, justifying the practice, on the authority of some distinguished practitioners, and the little danger, attendant on the operation.

Even Sabatier only objects to this proceeding, on the ground of the danger of mistaking a prolapsus of the uterus, for one of the vagina. However, no modern surgeons in this country would hesitate about rejecting such an operation, and leaving the sloughs to separate of themselves.

The prolapsus, arising from a hernia in the vagina, can only be ascertained by attending to the symptoms, which characterize this sort of rupture. See *Hernia*.

Consult particularly *Sabatier's Médecine Opératoire*, Tom. 2, p. 486, &c. Edit. 2. *Richter's Anfangsgründe der Wundarzneykunst*, B. 7, Vierte Kapitel.

VARICOCE'LE. (from *varix*, a distended vein, and *κηλη*, a tumour). Many writers mean by the term *varicocele*, a varicose enlargement of the spermatic veins, which latter affection, we have, with Celsus and Pott, treated of under the name of *Cirsocele*.

Pott remarks, that the varicocele (which is an enlargement and distention of the blood-vessels of the scrotum) is very seldom an original disease, independent of any other, and, when it is, is hardly an object of surgery. The blood-vessels of the scrotum are of different size in different people; and like the vessels in other parts of the body, are liable to become varicose; but, they are seldom so much enlarged, as to be troublesome, unless such enlargement is the consequence of a disease, either of the testicle, or spermatic chord. When this is the case, the original disease is what engages our attention, and not this simple effect of it; and, therefore, considered abstractedly, the varicocele is a disease of no importance. (*Pott's Chirurgical Works*, Vol. 2.)

VARICOSE ULCER. See *Ulcer*, and *Varicose Veins*.

VARICOSE VEINS. The term, *varix*, is applied by surgeons to the permanently dilated state of a vein, attended with an accumulation of dark-coloured blood, the circulation of which is materially retarded in the affected vessel. When veins are varicose, they are not only dilated, they are also evidently elongated, presenting a cylinder larger, than natural, irregular, and in several places studded with knots. They likewise make a variety of windings, and, coiling themselves, form actual tumours from the assemblage of their convolutions in one particular place. The trunk and branches of a vein, thus dilated and elongated, constitute a very distinct swelling, when they are numerous and confined to a certain part of the body. Indeed, when the diseased vessels are situated near the integuments, the surgeon can feel, and even see, the outlines of their tortuous course. These things, for instance, are remarkably obvious in the vena

saphena interna, where the affection is particularly common. This vessel may be observed to form in its course several of these swellings, in the interspaces of which, it runs in a very serpentine, tortuous manner.

Varices are most commonly observed in the lower extremities, reaching sometimes even as far up as the abdomen. They have however been noticed in the upper extremities, and, it is probable, that the whole venous system is susceptible of the affection. As a well informed writer observes; "The great venous trunks sometimes become varicose. When the disease is situated near the heart, it is attended with pulsation, which renders it liable to be mistaken for aneurism. Morgagni observed, that the jugular veins were occasionally very much dilated, and possessed a pulsation. (*Letter 8, art. 9, 10, 11*). He also relates a case, in which the vena azygos, for the length of a span, was so much dilated, that it might be compared with the vena cava. The patient died suddenly in consequence of the rupture of this varix into the right side of the chest. (*Letter 26, art. 29*.) A similar case is related by Portal, who also mentions an instance, in which the right subclavian vein was excessively dilated and burst into the chest. (*Cours d'Anatomie Médicale*, tom. 3, p. 354, 373.) Mr. Cline described in his lectures the case of a woman, who had a large pulsating tumour in her neck, which burst and proved fatal by hemorrhage. A sac proceeded from the internal jugular vein; the carotid artery was lodged in a groove at the posterior part of this sac. The veins of the upper extremity very rarely become varicose. Excepting cases of aneurismal varix, the only instance of this disease, with which I am acquainted, is mentioned by Petit. (*Traité des Maladies Chir.* tom. 2, p. 49.) In this case, a varix was situated at the bend of the arm: the patient was so fat, that no other vein could be found for the purpose of venesection, which operation Petit repeatedly performed by puncturing this varix. The superficial epigastric veins sometimes become varicose, but, the most frequent seats of this disease are the venæ saphenæ, the spermatic, and hemorrhoidal veins." (See *Hodgson's Treatise on the Diseases of Arteries and Veins*, p. 538—539.) The deep seated veins of the extremities seldom become varicose. The disease rarely occurs before the adult period of life, and its progress is extremely slow. It is very frequently remarked in pregnant women, who have passed a certain age; but, it is particularly unusual for it to happen in young women, even during a series of repeated pregnancies. Surgeons have not hitherto made out any very precise information, respecting the places, climates,

and kinds of constitution, which promote the occurrence of a varicose enlargement of the veins. Nor has it been well proved, that the disease often proceeds from swellings of the abdominal viscera, or any other species of tumour capable of mechanically obstructing the venous circulation. One or more veins of the same limb are at first most commonly affected with a slight degree of dilatation, without pain, or any sensation of uneasiness. This beginning change ordinarily advances with great slowness, except in cases, where it accompanies pregnancy, in which circumstance, one, or both the lower extremities, as early as the first months, are frequently seen covered with largely dilated veins, or even with tumours formed by an assemblage of varices. The veins gradually become more and more distended, lengthened, coiled up, and tortuous. The patient then begins to complain of a sense of heaviness, numbness, and sometimes of very acute wandering pain, through the whole of the affected limb. In a more advanced stage, in proportion as the varices increase, and especially when the dilated veins actually form tumours, the limb swells, and becomes more or less œdematous according to the extent of the disease, and the time which it has existed. M. Delpech thinks, however, that the œdema in this case is not such as to justify the conclusion, that the increased size of the veins, and the way in which they distend the integuments, produce a mechanical interruption of the function of the absorbent system. For, says he, we meet with, though not often, enormous varices, which are not attended with any swelling of the cellular substance; and we still more frequently see cases, in which there is a considerable degree of œdema, while the varices are scarcely remarkable. When the latter have prevailed a long while, and made much progress, the coats of the affected veins are not unfrequently thickened, swelled, and indurated, forming a sort of half-canal, or solid tube, which has been regarded as an excavation made by the pressure of the varix against the neighbouring bone. But, the same phenomena are equally observable, when varicose veins lie at a distance from any bone, against which they can be pressed. As Mr. Hodgson remarks, "the blood occasionally deposits strings of coagulum in varicose veins: when this is the case, the vessel is incapable of being emptied by pressure, and is firm to the touch. The deposition does not in general fill the vessel, but, by diminishing its calibre, it retards the flow of blood, and causes the dilatation to increase in the inferior portion of the vein, and in the branches, which open into it." (*On the Diseases of Arteries and Veins*, p. 541.) This gentleman has seen four cases, in

which the coagulum accumulated to such an extent, that the canals of the dilated vessels were obliterated, and a spontaneous cure was the consequence. The excessive distention of the coats of a superficial vein produces an inflammatory irritation, at first in the adjoining cellular membrane, and afterwards in the integuments. These organs become at first connected together by the adhesive inflammation; and, if the distention continue to operate, they may at length ulcerate, and burst, and hemorrhage be the consequence. In such cases, the effusion of blood has sometimes been very considerable; but, says M. Delpech, we have no example of its having proved dangerous. The syncope following it, or a moderate compression, has sufficed for its stoppage. A more common occurrence, than bleeding, is the coagulation of the blood in the cavity of a varicose vein. The vessel then becomes hard and incompressible, and it loses that elastic yielding softness, which renders it capable of being diminished by gentle pressure. If the parts be already inflamed, Delpech conceives, that the clot in the diseased vein may act as an extraneous body, and bring on ulceration, by the effects of which it is at last brought into view. In this sort of case, it is extremely uncommon for hemorrhage to occur; for, in general, the vessel has been already obliterated by the preceding inflammation. But, the ulcer itself is very difficult to heal, and may be kept up a long while by the œdematous swelling of the limb. Varices, or rather the œdema, which is the consequence of them, has the same effect upon every other species of ulcer, and even upon the most simple solution of continuity. While the swelling of the limb cannot be dispersed; while the edges of a solution of continuity are kept asunder by the tense state of the skin; and while the divided parts are irritated by this painful tension; every thing is unfavourable to cicatrization. Thus, we see the most simple wounds, which have been allowed to suppurate, and ulcers, which should have healed rapidly, continue uncured a great many years, merely because the limbs, on which they are situated, are affected with an œdematous swelling, the consequence of varices. Such is the condition of things in the case, which has been improperly named the *varicose ulcer*. (Delpech, *Précis des Maladies Chir.* tom. 3, sect. 8, art. 3.)

In the investigation of the causes of varices, it is usual to dwell very much upon the mechanical obstructions, which may affect the circulation of the blood in the veins. Surgeons have thought themselves justified in regarding this as the only cause, because a circular, moderate compression incontestably retards the course of the blood in these vessels, and produces

a temporary dilatation of them. The opinion has seemed also to derive confirmation from the knotty appearance of varicose veins, a circumstance, which has been accounted for by supposing, that the distention is greatest in the situation of the valves. Lastly, the idea is further supported by the well known fact of the frequent occurrence of varices during the state of pregnancy. But, it has not been remembered, that the use of garters, for example, is extremely common; yet varices of the legs are infinitely less frequent; that very large varices are met with in persons, who have never employed any kind of ligatures, to which the origin of the complaint can be imputed; that when the dilatation of the veins extends to the thighs and parietes of the abdomen, no causes of this description even admit of suspicion; that varicose veins are observable round several kinds of tumours, especially scirrhi, when there is no possibility of pointing out any mechanical obstruction to the circulation of the blood; that varices sometimes make their appearance at the commencement of pregnancy, and long before the enlargement of the womb can impede the free return of the blood through the veins in the pelvis; that nothing is more unusual, than a varicose dilatation of the veins of the lower extremities in consequence of swellings of the abdominal viscera; and, lastly, it has been forgotten, that the knots of the dilated veins are far too numerous to admit of being ascribed to the resistance of the valves. It cannot be denied, that pressure, applied in the track of the vessels, tends to promote their dilatation: but, it can neither be considered as the only cause, nor as the principal one. The foregoing observations, made by Delpech, render it probable, that some unknown general cause is concerned in producing varices, the formation of which may also be facilitated by the impediments to the free return of the blood, occasioned by certain attitudes, and particular articles of clothing.

Mr. Hodgson conceives it probable, that, in some instances, the valves are ruptured; in consequence of muscular exertions, or external violence, in which cases, the pressure of the column of blood is the first cause of the dilatation of the veins. Sometimes also the disease appears to arise from preternatural weakness in the coats of the veins, as, in those instances, in which, without any evident cause, it exists in various parts of the same person. (*Treatise on the Diseases of Arteries and Veins*, p. 537.)

Experience proves, says Delpech, that there is no certain mode of curing varices, strictly so called, which he thinks cannot be wondered at, since the nature and causes of the disease are completely unknown.

The same source of knowledge, however, also proves, that the increase in the dilatation of varicose veins may be retarded, and that the œdematous swelling, attendant on the complaint, may be beneficially opposed. But, these effects cannot be produced by resolvent, tonic, astringent applications, nor by aperient, diuretic, and purgative remedies, as some even of the latest writers so inconsiderately assert; but, only by means of methodical and permanent compression. When the whole of a limb, affected with varices, is subjected to this last mode of treatment, the dilated veins subside, the circulation is more regularly performed, and the œdema and pain cease. There is not (says Delpech) any better method of healing the solutions of continuity in the soft parts, produced, or kept up, by the varicose state of the limb, and its consequences. But, as soon as the compression is discontinued, the varices make their appearance again, the pain recurs, the œdema returns, and the ulcers, which were healed, break out afresh. Compression, therefore, which absolutely requires to be constantly employed, can be regarded only as a palliative, the more useful, indeed, inasmuch as the changes, which it brings about in the state of things, are nearly equivalent to a perfect cure.

Inflammation of the integuments covering a varix, or varicose tumour, cannot invariably be prevented by compression; nor will this treatment always succeed even in removing the intolerable pain, which sometimes attends numerous clusters of varicose veins. In the first case, rest and relaxing applications will often succeed; and in the second, the topical use of sedatives frequently gives relief. It has been proposed to puncture and empty varicose veins; but, if a temporary emptiness and relaxation of these vessels, which are rendered painful by their distention, could remove the pain for a time, things would fall into the old state again in the course of a few days. If it should appear, also, that the clotted blood had the effect of keeping up the unfavourable symptoms, it would be necessary to make a very free opening into the dilated vein, in order that the coagulum might be extracted. In such a case, it would be useless to tie the vessel above and below the opening, as has been recommended: the slightest compression is afterwards sufficient for the stoppage of the bleeding, and by the subsequent inflammation the vessel is certain of being obliterated.

We learn from Celsus, that the ancients were accustomed to remove varices by excision, or destroy them with the cautery. (*De Re Medicâ*, lib. 7, cap. 3.) When the vein was much convoluted, extirpation with the knife was preferred: but in other cases, the dilated vessel was exposed by

an incision, and then cauterized. Petit, Boyer, and many surgeons in this country, have also sometimes practised the operation of cutting out clusters of varicose veins.

Delpech remarks, that the extirpation of tumours, composed of numerous varices, has been practised, either for the purpose of removing the pain in the situation of the disease, or other inconveniences. This operation has been successfully performed; but it appears also not to have constantly had the effect of preventing the formation of new varices, and it has sometimes proved tedious, difficult, and severely painful in its execution. In fact, an erroneous judgment must necessarily be formed of the extent of these swellings, when they are judged of only from the appearance, which they present under the skin. When we attempt to operate (says Delpech), we may be led to organs, which ought not to be meddled with, and a long, and extremely painful, dissection may be found requisite. Besides, varices are not always confined to the superficial veins, and a relapse would be inevitable. These reflections tend to the conclusion, that operations of this sort should never be undertaken, except when the disease is accompanied with perilous symptoms, or nearly deprives the patient of the use of his limb.

It has been thought, that one of the established principles in the treatment of aneurisms might be advantageously extended to the cure of varicose veins. By tying the principal venous trunk above the point, to which the varicose affection reaches, it is said, that the course of the blood in the morbid vessels may be totally stopped; the column of this fluid contained in them made to coagulate; and the consequent obliteration of the vessels themselves accomplished.

The practice of tying veins for the cure of varices, appears to have been employed in the days of Paré and Dionis (*Cours d'Operations de Chirurgie*, p. 610.) who have accurately described the operation of tying and dividing the vein between the two ligatures. Sir Everard Home has related many cases of varicose veins in the leg, some of them being accompanied with tedious ulcers, in which, after tying the vena saphena major, where it passes over the inside of the knee, not only the dilatation of the veins of the leg was relieved, but the ulcers were readily healed.

This proceeding has unquestionably been sometimes followed with success; but, it has also had its failures. Amongst other evils, an inflammation of the tied vein has been observed, extending very far in the vessel, and succeeded by convulsions and death. Indeed, the dangers, arising from an inflammation of the internal coat of the

veins, are now generally acknowledged, and every endeavour should be made to avoid them. A case, which lately happened in one of the large hospitals of this metropolis, has fully proved them: we allude to the example, in which the femoral vein happened to be wounded in the operation for aneurism, and had a ligature applied round the small aperture accidentally made in it. Inflammation of its internal coat took place to a considerable extent, and the patient is supposed to have died of the indisposition resulting from it.

As Mr. Brodie observes, it seems to be now established by the experience of modern surgeons, that a mechanical injury, inflicted on the trunk of one of the larger veins, is liable to be followed by inflammation of its internal membrane, and a fever of a very serious nature; and the occasional occurrence of these symptoms after the ligature, or even the simple division of the vena saphæna, has made surgeons less confident, than formerly, of the propriety of attempting these operations for the relief of a varicose state of the branches of that vessel in the leg. Certain reflections, however, induced Mr. Brodie to think, that the same ill effects would not follow a similar operation performed on the branches themselves. "Where the whole of the veins of the leg are in a state of morbid dilatation, and the distress produced by the disease is not referred to any particular part, there seem to be no reasonable expectations of benefit, except from the uniform pressure of a well-applied bandage. But, not unfrequently, we find an ulcer, which is irritable, and difficult to heal on account of its connexion with some varicose vessels; or without being accompanied by an ulcer, there is a varix in one part of the leg, painful, and perhaps liable to bleed, while the veins in other parts are nearly in a natural state, or, at any rate, are not the source of particular uneasiness. In some of these cases, I formerly applied the caustic potash, so as to make a slough of the skin and veins beneath it; but, I found the relief, which the patient experienced from the cure of the varix, to afford but an inadequate compensation for the pain, to which he was subjected by the use of the caustic, and the inconvenience arising from the tedious healing of the ulcer, which remained after the separation of the slough.

"In other cases, I made an incision with a scalpel through the varix and skin over it. This destroyed the varix as completely as it was destroyed by the caustic, and I found it to be preferable to the use of the caustic, as the operation occasioned less pain, and as in consequence of there being no loss of substance, the wound was cicatrized in a much shorter space of time. I employed the operation, such as I have

described it, with advantage in several instances; but, some months ago, I made an improvement in the method of performing it, by which it is much simplified; rendered less formidable not only in appearance, but also in reality; and followed by an equally certain, but, more speedy cure.

"It is evident (says Mr. Brodie), that the extensive division of the skin over a varix can be attended with no advantage. On the contrary, there must be a disadvantage in it, as a certain time will necessarily be required for the cicatrization of the external wound. The improvement, to which I allude, consists in this; the varicose vessels are completely divided, while the skin over them is preserved entire, with the exception of a moderate puncture, which is necessary for the introduction of the instrument, with which the incision of the veins is effected. Thus the wound of the internal parts is placed under the most favourable circumstances for being healed, and the patient avoids the more tedious process, which is necessary for the cicatrization of a wound in the skin above.

"For this operation, I have generally employed a narrow, sharp-pointed bistoury, slightly curved, with its cutting edge on the convex side.—Having ascertained the precise situation of the vein, or cluster of veins, from which the distress of the patient appears principally to arise, I introduce the point of the bistoury through the skin on one side of the varix, and pass it on between the skin and the vein, with one of the flat surfaces turned forwards, and the other backwards, until it reaches the opposite side. I then turn the cutting edge of the bistoury backwards, and in withdrawing the instrument, the division of the varix is effected. The patient experiences pain, which is occasionally severe, but subsides in the course of a short time. There is always hemorrhage, which would be often profuse, if neglected, but which is readily stopped by a moderate pressure, made by means of a compress and bandage carefully applied." Mr. Brodie particularly enjoins the necessity of keeping the patient quietly in bed for four or five days after the operation, and removing the bandage and first dressings with the utmost care and gentleness. He also cautions surgeons not to make the incision more deeply, than absolutely necessary. Inflammation of the coats of the veins has not occurred in any of the cases, in which M. Brodie has adopted this method of treatment. This gentleman wishes it to be understood, however, that he does not recommend the practice indiscriminately, but with a due attention to the circumstances of each individual case. "The cases, for which it is fitted, are, not those, in which the veins of the leg generally are varicose; or in which the patient has little, or no inconvenience

from the complaint; but those in which there is considerable pain referred to a particular varix; or in which hemorrhage is liable to take place from the giving way of the dilated vessels; or in which they occasion an irritable and obstinate varicose ulcer." (See *Medico-Chir. Trans.* Vol. 7. p. 195, *et seq.*)

On the subject of cutting through veins affected with varix, it is proper to observe, that even this plan has been known to bring on severe and fatal symptoms. Cases confirming this fact are recorded in a valuable modern work, which should be in the hands of every practical surgeon. (See *Hodgson's Treatise on the Diseases of Arteries and Veins*, p. 555, *et seq.*) It is but justice to state, however, that, in these examples, Mr. Brodie's manner of doing the operation was not adopted.

As we have already noticed, cases of spontaneous varix in the veins of the arm are rarely observed. When these vessels become varicose, it is almost always in consequence of a communication being formed, in the operation of venesection, between the brachial artery and one of the veins at the bend of the arm. The superficial veins in this situation then become more or less dilated, by the impulse of the stream of arterial blood, which is thrown into them. There is however a good deal of difference, between these accidental varices, actually induced by a mechanical cause, and those which originate spontaneously, or from causes not very clearly understood. The former never acquire the size, which the latter often attain; they never exceed a certain magnitude, whether pressure be employed or not; they never form tumours composed of an assemblage of varicose veins; they are never filled with tough coagula of blood; their coats are never thickened, nor constitute the solid half canal remarked in the other species of varices; the skin, which covers them, is not disposed to inflame and ulcerate; they are not subject to occasional hemorrhage; and the limb is not affected with any œdematous swelling. (See *Delpech Traité des Maladies Chir.* Tom. 3, p. 261.) These circumstances must render it sufficiently evident, that all surgical interference in such a case would be entirely unnecessary.

For additional observations, connected with the subject of varicose veins, see the articles, *Aneurism*, where the aneurismal varix is described; *Cirsocoele*, where the varix of the spermatic chord is treated of; *Hemorrhoids*, where the diseased and enlarged veins of the rectum are considered; *Varicocoele*, where those of the scrotum are noticed.

VARIX. (from *varius*, unequal.) The term *varices* is applied to a kind of knotty, unequal, dark-coloured swellings, arising

from a morbid dilatation of veins. (See *Varicose Veins*.)

VEINS, DISEASES OF. Many diseases of veins are noticed in various parts of this Dictionary. For instance, the Aneurismal Varix is particularly described in the article *Aneurism*; the inflammation of the membranous lining of veins is noticed under the head of *Bleeding*, of which operation it is an occasional ill consequence. The varicose affection of the veins of the testicle is treated of in *Cirsocele*. Diseases of the veins of the rectum, are considered in the observations on *Hemorrhoids*. The nature, symptoms, and treatment, of varices in general are explained in the article *Varicose Veins*. I shall now briefly annex a few additional remarks on the principal diseases of the venous system, in order to render what has been already stated in other parts of the work more complete.

It is justly observed by Mr. Hodgson, that "the veins are liable to all those morbid changes, which are common to soft parts in general; but, the membranous lining of these vessels is peculiarly susceptible of inflammation. When a vein is wounded, the inflammation, which is the effect of the injury, sometimes extends along the lining of the vessel, into the principal venous trunks, and in some instances even to the membrane, which lines the cavities of the heart. This inflammation sometimes produces an effusion of coagulating lymph, by which the opposite sides of the vein are united, so as to obliterate the tube; in this manner a great extent of the vessel is occasionally converted into a solid cord. In some instances, the secretion of pus into the cavity of the vessel is the consequence of inflammation of the membranous lining of veins: under these circumstances, the matter is either mixed with the circulating blood, or, the inflammation having produced adhesion of the sides of the vessel at certain intervals, boundaries are formed to the collection of pus, which in this manner form a chain of abscesses in the course of the vessel.

"When the inflammation of veins is not very extensive, its symptoms are the same as those of local inflammation in general; but, when the inflammation extends into the principal venous trunks, and pus is secreted into the vessel, it is accompanied with a high degree of constitutional irritation, and with symptoms, which bear a striking resemblance to those of typhus fever." (See *Hodgson's Treatise on the Diseases of Arteries and Veins*, p. 511—512.)

I was lately informed of a case, in which a patient, who had undergone the operation for the cure of an aneurism in the thigh, died in consequence of an inflammation, which soon afterwards affected the lining of the femoral vein, and extended a consi-

derable way upwards towards the heart. In the operation, the vein had been accidentally punctured, and in order to stop the bleeding from it, the little opening was surrounded and tied with a very fine ligature, the vessel being left in a pervious state. This case happened in one of the principal hospitals of London, and it tends to confirm a fact, which is now well known to surgeons, that the application of ligatures to veins is by no means exempt from the risk of very serious and even fatal consequences. Hence, arises one of the most weighty objections, which have been urged against the practice of tying the trunks of varicose veins, with a view of curing the morbid dilatation of these vessels, and its effects upon the limb.

Inflammation frequently produces a thickening of the coats of the veins, as well as adhesion of their sides, and obliteration of their cavities. Indeed, in some instances, these vessels have been found to resemble arteries in the thickness of their coats, and in retaining a circular form when cut across. (*Hodgson, op. cit. p. 513.*)

Ulceration sometimes extends to the coats of veins, and, by exposing their cavities, gives rise to hemorrhage. In certain examples, it commences in the membranous lining, and destroys the other coats. In general, however, the adhesive inflammation precedes the ulcerative, and by obliterating the cavities of these vessels, prevents the occurrence of hemorrhage. When sphacelation takes place in the vicinity of veins, their cavities, like those of arteries under similar circumstances, are filled with extensive plugs of coagulum, which prevent hemorrhage upon the separation of the mortified part.

Veins are sometimes ruptured, without any previous morbid alteration in their structure, and the accident may be induced by muscular exertions, external violence, the sudden effects of the cold bath, &c.

Although a deposition of calcareous matter almost invariably takes place in the arteries of persons advanced in life, it is an extremely rare occurrence in the coats of veins.

Loose calculi have been found in the cavities of veins.

Tumours sometimes grow from the lining of veins. In a case of scirrhus pylorus, Mr. Hodgson found a tumour, larger than a hazel nut, growing from the lining of the splenic vein, and resembling in its appearance and consistence the disease, which existed at the pylorus. (*P. 524.*)

The venous, like the arterial system, appears to be capable of carrying on a collateral circulation, when any part of it is impervious. Even after the obliteration of the vena cava inferior, the blood has been known to be conveyed with facility to the

heart through the lumbar veins and vena azygos. In the case, recorded by Dr. Baillie, (*Trans. of a Society for the Improvement of Medical and Chir. Knowledge, Vol. 1, p. 127*) it is remarkable, that the vena cava inferior was obliterated where the venæ cavæ hepaticæ opened into it, so that not only the blood from the lower extremities, but also that from the liver, must have passed through collateral channels to the heart.

For a great deal of important additional information on the foregoing topics, I must refer to Mr. Hodgson's excellent Treatise on the Diseases of Arteries and Veins.

VENEREAL DISEASE. (*Lues Venerea. Morbus Gallicus. Syphilis, or Siphilis.*) About the year 1494, or 1495, the venereal disease is said to have made its first appearance in Europe. Some writers are of opinion, that the distemper originally broke out at the siege of Naples; but, most of them have supposed, that, as Columbus returned from his first expedition to the West Indies, about the above period, his followers brought the disorder with them from the new to the old world. Other authors, among whom is Mr. B. Bell, maintain the opinion, that many arguments might be adduced to shew, that the venereal disease was well known upon the old continent, and that it prevailed among the Jews, Greeks, and Romans, and their descendants, long before the discovery of America.

Marcellus Cumanus, Johannes de Vigo, and other early writers on the lues venerea, have left an account of some of the symptoms, and their description, as far as it extends, is found to agree with the appearances, observed even at the present day. Marcellus remarks: "I observed many of the officers and foot soldiers in Milan, while I was in the camp at Navarre, to have several scabs, or pustules, breaking out on the face, and spreading all over the rest of their bodies. The first of which appeared usually under the præputium, or on the outside, like a grain of millet, sometimes behind the glans, with a small itching. At other times, a single pustule would arise, like a little bladder, without much pain, but, itching also. If rubbed, or scratched, there arose an ulcer, corrosive and smarting, like the sting of an ant." &c. (*Vide Astruc, Vol. 2, p. 226, translated by Dr. Barrowby.*)

Johannes de Vigo notices the way in which the disease is communicated by a chancre, in a still more particular and accurate manner: *ejus origo in partibus genitalibus, viz. in vulvâ in mulieribus, et in virgâ in hominibus, semper ferè fuit cum pustulis parvis, interdum lividi coloris, aliquando nigri, nonnunquam subalbidi cum callositate eas circumdante.* De Morbo Gallico. These quotations prove, that the venereal disease was propa-

gated in the beginning, as it now is, by what the old writers called a *pustule*, and we name a *chancre*.

The venereal disease arises from a morbid poison, which when applied to the human body, has the power of propagating, or multiplying itself, and is capable of acting both locally and constitutionally.

As Mr. Hunter remarks, in whatever manner the venereal poison arose, it certainly began in the human race, as no other animal seems capable of being affected by it. The parts of generation were, probably, also, the first affected; for, if the disease had taken place in any other part of the body, in all probability, it would never have gone further, than the person in whom it first arose. However, since it was situated in the parts of generation, where the only natural connexion takes place, between one human being and another, except that between the mother and child, it was in the most favourable situation for being propagated; and Mr. Hunter infers, also, that the first effects of the disease must have been local, in consequence of the fact, now well established, that none of the constitutional effects are communicable to other persons.

The particular properties of the venereal poison are quite unknown, its effects on the human body being the only information which we possess concerning it. Mr. Hunter says, that it is commonly in the form of pus, or mixed with pus, or some other secretion. The virus excites, in most cases, an inflammation in the parts contaminated, which inflammation is attended with a specific mode of action, which is different from all other actions attending inflammation, and which, according to Mr. Hunter, produces the specific quality in the matter.

The formation of matter, though a general, is not a very constant attendant on this disease; for, inflammation, produced by the venereal poison, sometimes does not terminate in suppuration. But, if Mr. Hunter's sentiments are correct, it is the matter produced, whether with, or without inflammation, which alone contains the poison. Hence, a person, having the venereal irritation in any form, not attended with a discharge, cannot communicate the disease to another. In proof of this doctrine, the above-mentioned distinguished writer states, that, though married men often contract the disease, and continue to cohabit with their wives, even for weeks, yet, in the whole of his practice, he never once found, that the complaint was communicated under such circumstances, except when connexion had been continued, after the discharge had appeared.

That excellent surgeon, Mr. Hey of

Leeds, has however given it as his opinion, founded upon several instances, that a man may communicate the lues venerea, after all the symptoms of the disease have been removed, and he is judged to be in perfect health. (See *Medical and Chir. Trans.* Vol. 7, p. 547.) This sentiment appears so repugnant to every thing, which has hitherto been taught upon the subject, that surgeons should not be too hasty in adopting it. The very case, which Mr. Hey has adduced to prove the occurrence, is decidedly inadequate to the intended purpose, in consequence of the impossibility of trusting to the accounts, which patients give of themselves in cases of this description. In the case, recited by Mr. Hey, the gentleman might have had some venereal affection at the period of, or subsequently to, his marriage; and yet his feelings, and a sense of the disgrace of infecting a virtuous woman might compel him to conceal the real truth from his surgeon. Again, it is to be remembered, that the lady herself might have deviated from the path of chastity, and exposed herself to infection; and, if she had done so, she would have informed neither her husband, nor Mr. Hey. I confess, it is painful at all times to suspect the veracity and honour of individuals, whose situations in life are respectable; but, whenever an occurrence takes place, which is known to be contrary to the known laws of disease, every possibility is to be recollected, in order to avoid the necessity of admitting doctrines, which do not coincide with the facts of general experience.

Mr. Hey believes in the possibility of the venereal disease being communicated to the fœtus in utero by the mother. An universal desquamation of the cuticle; a hoarse squeaking voice; copper-coloured blotches; a scaly eruption upon the chin; and an unnatural redness of the anus; are the common symptoms, which Mr. Hey sets down as proofs of syphilis in very young infants, which have been thus infected, and his sentiment is favoured by these complaints having yielded to small doses of the submuriate of mercury, the hydrargyrus cum creta, &c. (See *Medical and Chir. Trans.* Vol. 7, p. 542—548, &c.)

It is possible to conceive, that the venereal poison may be in so diluted a state, as to be quite incapable of exciting any degree of irritation, and, consequently, that no effects would be produced. However, when the poison has the power of irritating the part to which it is applied, the same consequences will follow, whether from a large, or small quantity; from a strong, or weak solution.

The same matter, however, may affect different persons very differently. Two men sometimes have connexion with the same woman; both catch the disease; but,

one may have very severe, the other exceedingly mild symptoms. Mr. Hunter adds, that he has known one man give the disease to different women, and some of the women have had it with great severity, while others have suffered very slightly.

I think there cannot be a doubt, that climate and constitution have important influence over the venereal disease. It is a well known fact, that, in all warm countries, this disorder, as far as it regards the natives, and those who have been long settled there, is not only much milder in its symptoms, but much more easy of cure. In the West Indies, the Brazils, &c. it is not uncommonly cured by means of sarsaparilla, guaiacum, mezereon, &c. without a grain of mercury. It is to be understood, that this mildness of syphilitic complaints, and their facility of cure, in warm climates, do not extend to strangers, who have recently arrived there. On the contrary, these persons, when infected in such countries, suffer more from the virulence of the disease, than they would in their native climate. In Portugal, during the late war, the dreadful ravages of the venereal disease amongst the British soldiers, and its comparatively milder phenomena amongst the inhabitants of the country, were particularly noticed by all our surgeons employed on that service. “In the British army, (says Mr. Fergusson) it is probable, that more men have sustained the most melancholy of all mutilations, during the four years that it has been in Portugal, through this disease, than the registers of all the hospitals in England could produce for the last century; while venereal ulceration has not only been more intractable to the operation of mercury, than under similar circumstances at home, but the constitution, while strongly under the influence of the remedy, has become affected with the secondary symptoms in a proportion that could not have been expected. With the natives, on the contrary, the disease is very mild; curable, for the most part, by topical treatment alone, or wearing itself out when received into the constitution, after running a certain course, not always a very destructive one, without the use of any adequate mercurial remedy. This is seldom confessed by the practitioners of the country, who deeply feel and resent the ridicule, that has been cast upon them by foreigners, as much for the prevalence of the disease, as their supposed ignorance in treating it; and therefore they generally profess themselves to be advocates for mercury, and adepts in its use; but, the fact is not so, and I can aver, that the bulk of the people, and of all the military at the hospitals, even though a general order has been given out enjoining the use of

mercury, cure themselves, or get cured, by other means. I have now been upwards of two years at the head of their hospital department, and I can declare, that it never occurred to me, amongst all the venereal patients, whom in that time I have seen pass through the hospitals, to meet a single one under the influence of mercury, excepting those cases, wherein I myself have personally superintended its administration. They go out cured by topical remedies alone; and I have lived long enough amongst them to ascertain, that their return to hospital under such circumstances for secondary symptoms, is far from being an universal, or even a frequent occurrence. (*Fergusson, in Medical and Chirurgical Trans. Vol. 4, p. 1—2.*)

This gentleman infers, that, in Portugal, the disease is exhausted, and has lost a good deal of its virulence. He is led to adopt this opinion, not only from the facility of its cure, but also from the analogy of the natural small-pox, which, though the uses of inoculation and vaccination are well known to the regular faculty in Portugal, has been permitted, through the prejudices of the people, and defect of public spirit, to run its natural course unresisted amongst the bulk of the inhabitants, and has now changed into a mild disease, which does well under any mode of treatment. "Yet (says Mr. Fergusson) I have no doubt, that were this mild disease, or the mildest that was ever produced from the improved inoculation of England, communicated to a tribe of Indians, or to a plantation of negroes, or any other class of people, who had never before known the small pox, it would desolate with all the fury of pestilence, destroying wherever it could find victims, and never ceasing until it had destroyed the whole."

"All adventitious diseases, whether chronic or acute, all, in fact, that are not con-nate, endemic, and sporadic, appear more or less to run this course of exhausting themselves, while retained upon the same ground to which they have been transplanted; but, let the field be changed in any degree, and fresh sources of development be presented, they instantly resume their primary powers, and taking a fresh departure of violence, repeat the almost forgotten inflictions of their original visitation.—Similar to the above appears to be the inoculation of the exhausted syphilitic virus of Portugal (though evidently the same disease) into the constitution of the British, or other stranger. It is in some measure new, therefore unfriendly; and seems to have the power of exciting new actions of more than ordinary violence, and requiring curative means of more than common efficacy to arrest its progress. I need scarcely say, that this new organiza-

tion of disease in the stranger, cannot be combated by such means as the natives employ to cure themselves." (*Fergusson in Medical and Chir. Trans. Vol. 4, p. 7—10.*)

It is a great contested question, in the subject of the venereal disease, whether this malady and gonorrhœa arise from the same poison? Mr. Hunter acknowledges, that the opinion, of their originating from two distinct poisons, seems to have some foundation, when we consider the difference in the symptoms, and method of cure. But, the same author contends, that, if we take up this question upon other grounds, and, also, have recourse to experiments, the result of which we can also safely depend upon, we shall find this notion to be erroneous. I shall not repeat, in this place, the arguments, adduced by Hunter in support of the doctrine, that both diseases are produced by the same virus; the reader will find some notice taken of them in the article *Gonorrhœa*.

Mr. B. Bell, and several other writers, have supported an opinion, contrary to that promulgated by John Hunter, relative to the poison, from which lues venerea, and gonorrhœa arise, and, indeed, after impartially considering the evidence brought forward by the two opposite parties, I feel much inclined to believe, that the two diseases do not originate from the same virus. Mr. Hunter, it is true, has brought forward some observations tending to shew, that, a chancre and other venereal symptoms, following absorption from such chancre, might be communicated by inoculating a person with the matter of a gonorrhœa. However, in speaking of *gonorrhœa*, I have suggested some reasons for not placing implicit belief in the inferences, which Mr. Hunter has drawn.

Mr. B. Bell adduces some facts, from which an almost decisive conclusion may be made, that the poisons of the venereal disease, and the gonorrhœa, are entirely different and distinct. Mr. Bell observes, that, on a subject such as this, the names of persons, by whom the following experiments were conducted, cannot be mentioned; but, he is personally acquainted with all of them, and he believes his friend, Dr. Duncan, saw the progress of some of the cases. Mr. Bell knows, that all which they relate, may be with certainty relied on, and he explains, what was done, in nearly their own words.

One gentleman states: "My experiments were made a good many years ago, and were meant to form the subject of a paper for a medical society, of which I am a member. I had no theory to support, nor any other view in making them, than to support the opinion, at that time gene-

rally received among practitioners, namely, that lues venerea and gonorrhœa virulenta, are one and the same disease, arising from the same matter of contagion, acting in a different manner on different surfaces. I was soon, however, convinced, by the very distressful and unexpected event of my experiments of the fallacy of this opinion.

"Matter was taken upon the point of a probe, from a chancre on the glans penis, before any application was made to it, and completely introduced into the urethra, expecting thereby to produce a gonorrhœa. For the first eight days, I felt no kind of uneasiness; but, about this period, I was attacked with pain in passing my water. On dilating the urethra, as much as possible, nearly the whole of a large chancre was discovered, and, in a few days thereafter, a bubo formed in each groin. No discharge took place from the urethra, during the whole course of the disease; but another chancre was soon perceived in the opposite side of the urethra, and red precipitate was applied to it, as well as to the other, by means of a probe previously moistened for the purpose. Mercurial ointment was at the same time rubbed on the outside of each thigh, by which a profuse salivation was excited. The buboes, which, till then, had continued to increase, became stationary, and, at last, disappeared entirely; the chancres became clean, and, by a due continuance of mercury, a complete cure was at last obtained."

Mr. B. Bell informs us, that the next experiment was made with the matter of gonorrhœa; a portion of which was introduced between the prepuce and glans, and allowed to remain there without being disturbed. In the course of the second day, a slight degree of inflammation was produced, succeeded by a discharge of matter, which, in the course of two or three days, disappeared.

The same experiment was, by the same gentleman, repeated once and again, after rendering the parts tender, to which the matter of gonorrhœa had been applied; but, no chancre ever ensued from it.

Mr. B. Bell also acquaints us, that two young gentlemen, while prosecuting the study of medicine, became anxious to ascertain the point in question; with which view, they resolved on making the following experiments, at a time, when neither of them had ever laboured under either gonorrhœa, or syphilis, and both in these and in the preceding experiments, the matter of infection was taken from patients who had never made use of mercury.

A small dossil of lint, soaked in the matter of gonorrhœa, was by each of them

inserted between the prepuce and the glans, and allowed to remain on the same spot for the space of twenty-four hours. From this, they expected, that chancres would be produced; but, in the one, a very severe degree of inflammation ensued over the whole glans and præputium, giving all the appearance of, what is usually termed, *gonorrhœa spuria*. A considerable quantity of fetid matter was discharged from the surface of the inflamed parts, and, for several days, there was reason to fear, that an operation would be necessary for the removal of a paraphimosis. By the use of saturnine poultices, laxatives, and low diet, however, the inflammation abated, the discharge ceased, no chancre took place, and the case got entirely well.

The other gentleman, says Mr. B. Bell, was not so fortunate. The external inflammation, indeed, was slight, but, by the matter finding access to the urethra, he was attacked on the second day with a severe degree of gonorrhœa, which continued for a considerable time to give him a great deal of distress, nor did he, for upwards of a year, get entirely free from it.

The latter gentleman impressed with a sense of the imprudence and hazard of all such experiments, could not be prevailed upon to carry them further, although they were prosecuted by his friend. This young man, soon after the inflammation, arising from his first experiment, had been removed, inserted the matter of gonorrhœa on the point of a lancet, beneath the skin of the præputium, and, likewise, into the substance of the glans; but, although this was repeated three different times no chancres ensued. A slight degree of inflammation was excited: but it soon disappeared, without any thing being done for it. His last experiment was attended with more serious consequences. The matter of a chancre was inserted on the point of a probe to the depth of a quarter of an inch, or more, in the urethra. No symptoms of gonorrhœa ensued; but, in the course of five, or six days, a painful inflammatory chancre was perceived on the spot, to which the matter was applied. To this succeeded a bubo, which ended in suppuration, notwithstanding the immediate application of mercury; and the sore, that was produced, proved both painful and tedious. Ulcers were at last perceived in the throat, nor was a cure obtained, till a very large quantity of mercury had been given and the patient kept in close confinement for thirteen weeks. (*Treatise on Gonorrhœa Virulenta and Lues Venerea*, Vol. 1, Edit. 2, p. 438, &c.)

Some have supposed that the poisonous quality of venereal matter arises

from a fermentation taking place in it as soon as it is formed. However, Mr. Hunter conceives, that the animal body has a power of producing matter according to the irritation given; and that the living powers, whenever irritated in a particular manner, produce such an action in the parts, as to generate a matter, similar in quality to that which excited the action.

It does not seem necessary to adduce the arguments, by which the idea of fermentation being concerned in the production of the venereal virus, might be refuted, as no modern practitioner now defends the doctrine. Mr. Hunter was of opinion, that the effects, produced by the venereal poison, arise from its peculiar, or specific irritation, joined with the aptness of the living principle to be irritated by such a cause, and the parts, so irritated acting accordingly. Hence, he considered, that the venereal virus irritated the living parts in a manner peculiar to itself, and produced an inflammation, peculiar to that irritation, from which a matter is produced, peculiar to the inflammation.

The venereal poison is capable of affecting the human body in two different ways: locally, that is, in those parts only, to which it is first applied; and, constitutionally, that is, in consequence of the absorption of the venereal pus, which affects parts, while it is diffused in the circulation.

Though Mr. Hunter uses the term constitutional, he explains in a note, that the word is not altogether correctly applied, as every complaint of a venereal nature is truly local, and produced by the simple application of the poison to the parts. The latter circumstance may happen, either by the immediate contact of the matter with the skin, before any absorption has taken place, or it may happen by the matter coming into contact with such parts as are susceptible of the venereal disease, after absorption has taken place, and while the virus is circulating in the system.

Mr. Hunter believed, as the reader already understands, that gonorrhœa was only one form of the venereal disease. In gonorrhœa, he observes, there is a formation of matter without a breach in the solids, while, on the contrary, a chancre is attended with a breach of this kind; and, he imputed the two different ways, in which the disorder appears, not to any thing peculiar in the kind of poison applied, but, to the difference in the parts contaminated. When the poison was applied to a secreting surface, which had no cuticle, he believed, that, it never produced ulceration, but, only an

alteration in the quality of the secretion. Thus, in the urethra, instead of mucus, pus became secreted, and a gonorrhœa arose. On the other hand, Mr. Hunter thought, that, when the virus was applied to a surface, that is covered with a common cuticle, as the common skin of the body, ulceration would be the effect. In this manner, he accounts for the same poison producing two such different consequences, as gonorrhœa, and chancre.

OF CHANCRES.

From the account, already delivered, that the venereal disease can only be imparted from one person to another by the actual contact of the matter, it must be obvious, that the first effects of the disorder must in general make their appearance on the parts of generation, in consequence of the virus being applied to them during coition.

Mr. Hunter reminds us, however, that the penis, which in men, is the common seat of a chancre, is, like every other part of the body, liable to diseases of the ulcerative kind, and that, on account of some circumstances, it is rather more so than other parts. When attention is not paid to cleanliness, excoriations, or superficial ulcers often originate in consequence of such neglect. The genitals, also, like almost every other part that has been injured, when once they have suffered from the venereal disease, are very liable to ulcerate again. Since, therefore, the penis is not exempted from the common diseases of the body, Mr. Hunter very properly remarks, that an opinion concerning ulcers situated on it, must be formed with great attention, particularly, as every disease in this part is suspected to be venereal.

“Venereal ulcers (says Mr. Hunter) commonly have one character, which, however, is not entirely peculiar to them; for, many sores, that have no disposition to heal, (which is the case with a chancre) have so far the same character. A chancre has commonly a thickened base, and, although, in some, the common inflammation spreads much further, yet the specific is confined to this base.” (P. 215.)

Mr. Hunter notices, that there are three ways, in which chancres may be produced; first, by the poison being inserted into a wound; secondly, by being applied to a non-secreting surface; and, thirdly, by being applied to a common sore. To whichever of these three different surfaces it is applied, the pus produces its specific inflammation and ulceration, attended with a secretion of pus. The matter produced, in consequence of these different modes of

application, partakes of the same nature as the matter, which was applied, because, as Mr. Hunter observes, the irritations are alike.

Mr. Hunter takes notice, that the poison much more readily contaminates, when it is applied to a fresh wound, than to an ulcer.

Though chancres commonly occur on the parts of generation, this circumstance is entirely owing to these being the only parts, with which the virus ever comes into contact, the application being made during the connexion between the sexes. Every part of the body may be affected by the application of venereal matter to it, particularly when the cuticle is thin. Mr. Hunter mentions, his having seen on the red part of the lip a chancre, which was as broad as a sixpence. The venereal virus had most probably been inadvertently applied to the part by the patient's own fingers. Mr. Hunter had not the least doubt of the sore being really a chancre; for, besides its diseased appearance, it was attended with a bubo in one of the glands under the lower jaw.

Chancres have frequently been seen on the fingers, particularly when there has been any previous cut, or scratch on these parts, and they have been employed in this state in dressing venereal sores.

Mr. Hunter computed, that claps occur more frequently, than chancres, in the proportion of four or five to one. As this celebrated writer conceived, that both these diseases originated from the same virus, which only produced different effects by its having to act on a secreting, or non-secreting surface, he attempts to explain the less frequent occurrence of chancres by the operation of the venereal poison, being often prevented by the intervention of the cuticle.

The same author states, that, in men, chancres generally make their appearance on the frænum, glans penis, prepuce, or on the common skin of the body of the penis; and, sometimes, on the fore part of the scrotum; but, he thought, that such sores took place most frequently on the frænum, and in the angle, between the penis and glans. He refers the cause of the venereal poison affecting these parts to the manner, in which the disease is caught, and not to any specific tendency in these parts to catch the complaint; and he imputes the circumstance of the frænum being more frequently affected, than other parts of the penis, to the external form of that part being irregular, and allowing the venereal matter to lie undisturbed in its folds. Thus the virus has time to irritate, and inflame the parts, and to produce the suppurative and ulcerative inflammation in them,

Mr. Hunter next observes, that the interval, between the application of the poison, and its effects upon the parts, is uncertain; but, that, on the whole, a chancre is longer in appearing, than a gonorrhœa. However, the nature of the parts affected makes some difference. When a chancre occurs on the frænum, or at the termination of the prepuce, in the glans, the disease in general comes on earlier; these parts being more easily affected, than either the glans penis, common skin of this organ, or the scrotum.

Mr. Hunter adds, that, in some cases, in which both the glans and prepuce were contaminated from the same application of the poison, the chancre made its appearance earlier on the latter part.

Mr. Hunter states his having been acquainted with some instances, in which chancres appeared twenty-four hours after the application of the matter; and with others, in which an interval of seven weeks, and even two months elapsed, between the time of contamination and that, when the chancre commenced.

A chancre first begins with an itching in the part. When the inflammation is on the glans penis, a small pimple full of matter, generally arises, without much hardness, or seeming inflammation, and with very little tumefaction; for, the glans penis is not so apt to swell, in consequence of inflammation, as many other parts are, especially, the prepuce. Mr. Hunter also explains, that chancres, situated on the glans, are not attended with so much pain and inconvenience, as sores of this nature on the prepuce. When chancres occur on the frænum, or, particularly, on the prepuce, a much more considerable degree of inflammation soon follows, attended with effects, more extensive and visible. These latter parts, being composed of very loose cellular membrane, afford a ready passage for the extravasated fluids. The itching is gradually converted into pain; in some cases, the surface of the prepuce is excoriated, and afterwards ulcerates; while, in other examples, a small pimple or abscess appears, as on the glans, and then turns into an ulcer. The parts become affected with a thickening, which, at first, while of the true venereal kind, is very circumscribed; not diffusing itself, as Mr. Hunter observes, gradually and imperceptibly into the surrounding parts; but, terminating rather abruptly. Its base is hard, and the edges a little prominent. When it begins on the frænum, or, near it, that part is very commonly wholly destroyed, or a hole is often made through it by ulceration. Mr. Hunter thought it better, in general, under the latter circumstance, to divide the part at once.

When the venereal matter is applied to the body of the penis, or front of the scrotum, where the cuticle is thicker, than that of the glans penis and prepuce, the chancre generally makes its appearance in the form of a pimple, which commonly forms a scab, in consequence of evaporation. The first scab is generally rubbed off; after which a second, still larger, one is produced.

When the disease is more advanced, it is often attended with such inflammation as is peculiar to the habit, becoming in many instances more diffused, and often producing phymosis, and paraphymosis. However, says Mr. Hunter, there is yet a hardness around the sores, which is peculiar to such as are caused by the venereal virus, particularly those on the prepuce.

The local, or immediate effects of the venereal disease are seldom wholly specific; but, are usually attended both with the specific and constitutional inflammation. Hence, Mr. Hunter, advises particular attention to be paid to the manner, in which a chancre first appears, and to its progress. If the inflammation spreads in a quick and considerable way, the constitution must be more disposed to inflammation, than is natural. When the pain is severe, Mr. Hunter remarks, there is a strong disposition to irritation. Chancres also, sometimes, soon begin to slough, there being a strong tendency to mortification.

It is also observed by Mr. Hunter, that when there is a considerable loss of substance, either from sloughing or ulceration, a profuse bleeding is no uncommon circumstance, more especially, when the ulcer is on the glans. The adhesive inflammation does not appear to take place sufficiently to unite the veins of this part of the penis, so as to prevent their cavity from being exposed, and the blood escapes from the corpus spongiosum urethræ. The ulcers, or sloughs, often extend as deeply as the corpus cavernosum penis, and similar bleedings are the consequence.

With respect to chancres in women, the labia and nymphæ, like the glans penis in men, are subject to ulceration, and the ulcerations are generally more numerous in females, than males, in consequence of the surface, on which the sores are liable to form, being much larger. As Mr. Hunter observes, chancres are occasionally situated on the edge of the labia; sometimes on the outside of these parts; and even on the perinæum. When the sores are formed on the inside of the labia or nymphæ, they can never dry, or scab; but, when they are externally situated, the matter may dry on them, and produce a scab, just as happens, with respect to chancres

situated on the scrotum, or body of the penis.

Mr. Hunter remarks, that the venereal matter from these sores is very apt to run down the perineum to the anus, and excoriate the parts, especially, about the anus, where the skin is thin, and where chancres are liable to be thus occasioned.

Chancres have been noticed in the vagina; but, Mr. Hunter suspected, that they were not original ones; but, that they had spread to this situation from the inside of the labia.

Before any of the virus has been taken up by the absorbents, and conveyed into the circulation, a chancre is entirely a local affection.

TREATMENT OF CHANCRES.

It was one of Mr. Hunter's opinions, that the ulceration, arising from venereal inflammation, generally, if not always, continues, till cured by art, and his theoretical reason for this circumstance was, that, as the inflammation in the chancre spreads, it is always attacking new ground, so as to produce a succession of irritations, and hinder the disease from curing itself.

It was no doubt the foregoing opinion of Mr. Hunter, which formed the authority for the position, which was always strenuously insisted upon in the surgical lectures, which I some years ago attended in London, viz. that all venereal complaints, when not counteracted by remedies, invariably grow progressively and regularly worse and worse. But, modern experience now apprises us, that this doctrine is far from being correct. The paper of Mr. Fergusson has already assured us, that in Portugal, the disease in its primary state amongst the natives is curable without mercury, and by simple topical treatment; that the antisymphilitic woods, combined with sudorifics, are an adequate remedy for constitutional symptoms; and that the virulence of the disease has there been so much mitigated, that, after running a certain course (commonly a mild one) through the respective orders of parts, according to the known laws of its progress, it exhausts itself, and ceases spontaneously. (See *Medical and Chir. Trans.* Vol. 4, p. 2—5.) In the last edition of the *First Lines of the Practice of Surgery*, it was sufficiently proved, from several conclusions drawn from the writings of Mr. Pearson, (*Obs. on the Effects of Various Articles in the Cure of Lues Venerea*.) that venereal sores could be benefited, and even healed, under the use of several inert insignificant medicines. Such was the state of our knowledge, when some well in-

formed surgeons in this country determined to try here what would be the result of omitting mercury altogether, and trusting to simple topical dressings and cleanliness. Mr. Rose, one of the surgeons of the guards, has in particular prosecuted this interesting enquiry to an extent, which leaves no doubt of the fact, that both primary and secondary venereal sores will generally heal of themselves, not only without the assistance of mercury, but without that of any other means, excepting cleanliness and ordinary dressings. It is acknowledged, however, that, in this way the cure is more slowly effected.

I am also informed, that buboes, eruptions, and sore throats do occur, under this plan of treatment, with about as much frequency as when mercury is used; but, that these consequences also after a time, (sometimes, it is true, a considerable time) do spontaneously get well.

With respect to nodes, it is said, they hardly ever follow, when the disease is thus left to itself, which, if positively a fact, leaves no doubt in my own mind, that many nodes are actually induced by the immoderate use of mercury in the primary stages of syphilis; that is to say, the system is so impaired by the long and excessive exhibition of this mineral, that, when the patient discontinues it, and exposes himself to the damp and cold, his bones begin to suffer.

Although the above facts serve to correct the mistaken notion, that chancres always get worse and worse, without the aid of medicine, they do not altogether justify the entire discontinuance of the employment of mercury, because, it is admitted, that, if this medicine be not given, the cure is much slower, and sometimes very tedious. These important facts, however, have a strong tendency to prove, that, even in this country, mercury should never be given in any syphilitic cases, except in small moderate quantities, and that the practice of producing violent salivations ought to be for ever exploded.

When I was an apprentice at St. Bartholomew's Hospital, most of the venereal patients in that establishment were seen with their ulcerated tongues hanging out of their mouths; their faces prodigiously swelled; and their saliva flowing out in streams. The wards were not sufficiently ventilated, and the stench was so great, that the places well deserved the appellation of *foul*. Yet, notwithstanding mercury was thus *pushed*, (as the phrase was) it was then common to see many patients suffer the most dreadful of mutilations, in consequence of sloughing ulcers of the penis; other patients, whose noses and palates were lost; others, who were co-

vered with nodes and dreadful phagedenic sores.

Happily, at the present day, this attachment to violent salivations no longer prevails; simple excoriations and common ulcers are more attentively discriminated from truly venereal sores; and even in decidedly syphilitic cases, mercury is seldom given except in very moderate doses, or such quantities as only gently affect the gums and salivary glands. The surgeons being now no longer blinded with the continual fears of syphilis, avoid the very mode of practice, which was itself the cause of all the aggravated forms of the disease. The consequence is that very bad instances of its ravages are now hardly ever observed there, and the few aggravated cases, which are met with, are generally in that state previously to their admission.

Having introduced these general remarks as a caution to surgeons to beware of the baneful plan of loading patients with mercury, I consider the reader better prepared to judge of the goodness of many of the subsequent observations and opinions, delivered by Mr. Hunter. The greater present mildness of syphilitic diseases in England, I ascribe chiefly to the more judicious treatment now adopted, and not to any change, or modification, in the nature of the disorder. There are others, however, who may think as Mr. Fergusson does with regard to syphilis in Portugal, that the disease has exhausted a great deal of its virulence from long continuance amongst us. But, before we are altogether justified in drawing such a conclusion, we must forget all the bad practice, which prevailed in former days, and which in my opinion is sufficient to account for the more severe forms, in which syphilis then presented itself.

We have already noticed, that chancres are not wholly venereal, but are attended with effects, dependent on constitutional peculiarities, to which the variety in the treatment must be adapted. The venereal symptoms, abstractedly considered, may be cured by mercury; but, the treatment of the symptoms, which depend on peculiarity of constitution, have no specific remedy, and demand different means in different cases.

Though the treatment of a chancre may be attempted both constitutionally and locally, it is commonly a considerable time before the sores appear to be affected by mercury. Sometimes the constitution must be under the influence of mercury for three or four weeks, or even longer, before a chancre begins to separate its discharge from its surface, so as to look red, and exhibit a living surface; but,

says Mr. Hunter, when once it does change, its progress towards healing is more rapid. This author describes a chancre as being generally much longer in getting well, than the other local effects of the venereal disease, arising from the absorption of the poison into the constitution.

Chancres (observes the same celebrated writer) admit of two modes of treatment. The object of one is to destroy or remove them by means of escharotics, or by extirpation. That of the other is to overcome the venereal irritation by means of the specific remedy for the syphilitic poison.

That chancres are local complaints, is confirmed by the circumstance of their admitting of being destroyed, or cured merely by local treatment. It has been a question, whether mercury should ever be locally applied to chancres or not. On this subject, Mr. Hunter considers, that, in the cure of such sores, there are two objects to be aimed at; one is the cure of the chancre itself; the other is the prevention of a contamination of the habit.

The cure of the chancre is to be effected by mercury, applied either in external dressings, or, internally, through the circulation, or in both ways. The preservation of the constitution from contamination is to be accomplished, first by shortening the duration of the chancre, which shortens the opportunity for absorption; and secondly, by internal medicine, which must be in proportion to the time, that the absorption may have been going on.

If, says Mr. Hunter, the power of a chancre to contaminate the constitution, or, what is the same thing, if the quantity of the virus absorbed is proportioned to the size of the chancre, and the time of absorption, which most probably it is, then whatever shortens the time, must diminish the above power, or the quantity of the poison absorbed. Also, if the quantity of mercury, necessary to preserve the constitution, is proportioned to the quantity of the virus absorbed, then whatever lessens the quantity absorbed, must proportionally preserve the constitution. For instance, says Mr. Hunter, if the power of a chancre to contaminate the constitution in four weeks is equal to four, and the quantity of mercury necessary to be given internally, both for the cure of the chancre and the preservation of the constitution, is also equal to four, then whatever shortens the duration of the chancre, must lessen in the same proportion the quantity of mercury necessary. Hence, if local applications, together with the internal use of mercury, will cure a chancre in three weeks, then it

will only be necessary to exhibit three-fourths of the quantity of mercury internally. Mr. Hunter observes, therefore, that local applications, inasmuch as they tend to shorten the duration of a chancre, shorten the duration of absorption, and, in this manner, shorten the necessity for the continuance of an internal course of mercury, all in the same proportion. For example, if four ounces of mercurial ointment will cure a chancre and preserve the constitution in four weeks, three ounces will be sufficient to preserve the constitution, if the cure of the chancre can be, by any other means, forwarded, so as to be effected in three weeks. Mr. Hunter affirms, that this is not speculation; but, the result of experience, and confirmed by the destruction of chancres.

DESTROYING CHANCRES.

Mr. Hunter notices, that the most simple method of treating a chancre is to destroy, or extirpate it, whereby it is reduced to the state of a common sore, or wound, and heals up as such. This can only be done on the first appearance of the chancre, when the surrounding parts are not yet contaminated; for, it is absolutely necessary to remove the whole of the diseased part, and this object is exceedingly difficult of accomplishment, when the disease has spread considerably. The plan may be effected either with the knife, or caustic. Mr. Hunter states, that, when the chancre is situated on the glans penis, touching the sore with the lunar caustic is preferable to cutting it away, because the hemorrhage from the cells of the glans would be considerable in the latter method.

The caustic will not give a great deal of pain, as the glans is not an exceedingly sensible part. The caustic employed should be pointed at the end, like a pencil, in order that it may only touch such parts as are really diseased. This treatment should be continued, till the surface of the sore looks red and healthy, after the separation of the last sloughs. When it has attained this condition, it will heal, like any other sore, made with caustic.

When the sore is on the prepuce, or the common skin of the penis, and, in an incipient state, the same practice may be adopted with success. When the chancre is large, however, it cannot be destroyed with the *argentum nitratum*, which does not extirpate the increasing sore deeply enough. In such cases, Mr. Hunter thought, that the *potassa cum calce* would answer very well. When the latter caustic cannot be conveniently em-

ployed, this author recommended the chancre to be cut away. He mentions his having taken out such a sore by dissection, and that the part afterwards healed with common dressings. However, says he, as our knowledge of the extent of the disease is not always certain; and as this uncertainty increases with the size of the chancre, the cure must be in some measure promoted by proper dressings, and, it will be prudent to dress the sore with mercurial ointment. When this plan is followed, Mr. Hunter believed, that there is but little danger of the constitution being infected, particularly, when the chancre has been destroyed almost immediately on its first appearance; for, then it is reasonable to conclude, that there has not been time for absorption to have taken place. But, observes the same author, as it must be in most cases uncertain, whether there has been absorption or not, this practice should not always be trusted to, and, perhaps, never should be relied in. Hence, even when the chancre has been destroyed in its incipient state, some mercury should be given from motives of prudence, the quantity of which medicine ought to be proportioned to the duration and progress of the sore. When the chancre is large, before it is extirpated, mercury is absolutely necessary, and Mr. Hunter conceived, that very little good is done by the extirpation.

LOCAL APPLICATIONS TO CHANCRES.

The cure of a chancre (says Mr. Hunter) is a different thing from its extirpation, and consists in destroying its venereal disposition, which object being effected, the parts heal of course, as far as they are venereal.

The employment of mercury, both as a topical application, and a constitutional remedy, is the best method of curing a chancre.

Mercurial ointments have been commonly used as dressings to chancres; but, Mr. Hunter was of opinion, that if the mercury were joined with watery substances, instead of oily ones, the application, by mixing with the matter, would be continued longer to the sore, and would prove more effectual. This, he observes, is one advantage, which poultices have over common dressings. He has often used mercury rubbed down with some conserve, instead of ointment, and it answered extremely well. Calomel used in the same way, and also the other preparations of mercury, mixed with mucilage, or honey, answer the same purpose. Such dressings, according to Mr. Hunter, will effect a cure, in cases,

which are truly venereal, and free from other morbid tendencies.

Some chancres are indolent, and require a little warm balsam or red precipitate to be joined with the mercurial dressing. Mr. Hunter says, that calomel mixed with salve is more active, than common mercurial ointment, and is attended with better effects, when the case requires stimulants.

Solutions of the sulphate of copper, acetite of copper, submuriate of mercury, &c. have been recommended. But, Mr. Hunter very judiciously observes, that, as all these applications are only of service in remedying any peculiar disposition of the parts, as they have no specific power over the venereal poison, and as such dispositions are innumerable, it is almost impossible to say, what applications will be effectual in every instance. Some kinds of dressings will answer in one state of the sore; some in another. The parts affected are often found extremely irritable, in which circumstance the mercury should be mixed with opium or preparations of lead.

Mr. Hunter was an advocate for changing the dressings, very often, because the matter separates them from the sore, so as to diminish their effects. He states, that changing the applications, thrice a day, will not be found too often, particularly, when they are in the form of an ointment.

When the venereal nature of a chancre is removed, the sore frequently becomes stationary, in which case Mr. Hunter observes, that new dispositions have been acquired, and the quantity of disease in the part has been increased. When chancres are only stationary, Mr. Hunter says, they may often be cured, by touching them slightly with the lunar caustic. No cicatrization, in this case, seems possible, till the contaminated surface, or the new flesh, which grows on that surface, has either been destroyed or altered.

It is often surprising, how quickly the sores heal up after being touched with the application. (See *Hunter on the Venereal Disease*.)

INTERNAL EXHIBITION OF MERCURY FOR CHANCRES.

At the same time that topical applications are made to chancres, mercury must be internally exhibited, both with a view of curing these ulcers, and preventing a lues venerea. Mr. Hunter believed, that the venereal disposition of the chancre would hardly ever withstand both local and internal mercurials.

When local applications cannot easily be made to chancres, as in cases of phy-

mosis, there still is a greater necessity for giving mercury internally, by which means, the cure may in the end be effected.

Mercury should always be given internally in every case of chancre, let it be ever so slight, and even when the sore has been destroyed on its very first appearance. The remedy should always be exhibited the whole time of the cure, and continued for some time after the chancre has healed; for, says Mr. Hunter, as there are, perhaps, few chancres without absorption of the matter, it becomes absolutely necessary to give mercury to act internally, in order to hinder the venereal disposition from forming. How much mercury should be thrown into the constitution in the cure of a chancre, with a view of keeping the system from being affected, cannot easily be determined, as there is no disease actually formed, by which we can be guided. Mr. Hunter states, that the quantity must in general be proportioned to the size, number, and duration, of the chancres; or, in other words, proportioned to the opportunity, which there has been given for absorption. From the facts, however, which we have already premised in this article, it is never advantageous to give mercury in such quantities, as will produce a violent salivation. Modern experience proves, that, in almost every instance, small doses will effect a cure more safely, than large immoderate quantities.

The mercury, which is exhibited to act internally, may be conveyed into the system, either by the skin, or stomach, according to circumstances, and, it should be so taken, as to produce a slight affection of the mouth.

Mr. Hunter next remarks, that when the sore has put on an healthy look, when the hard basis has become soft, and the ulcer has skinned over in a favourable manner, it may be regarded as cured.

The same distinguished writer notices, however, that, in very large chancres, it may not always be necessary to continue either the external or internal administration of mercury, till the sore is healed; for, the venereal action is just as soon destroyed in a large chancre, as it is in a small one, since every part of the sore is equally affected, by the medicine, and, of course, cured with equal expedition. But, in regard to cicatrization, circumstances are different, because a large sore is longer than a small one, in becoming covered with skin. Hence, Mr. Hunter very justly explains, that a large chancre may be deprived of its venereal action, long before it has healed; while, on the other hand, a small one may heal before the syphilitic affection

has been destroyed. In the latter case, this gentleman represents it as most prudent, both on account of the chancre and constitution, to continue the employment of mercury a little while after the sore is healed.

Mr. Hunter, in the valuable work, which he has left on the present subject, takes notice of sloughs, which occur in the tonsils, from the effect of mercury on the throat, and are apt to be mistaken for venereal complaints. He also mentions, that, sometimes, when the original chancre has been doing well, and been nearly healed, he has seen new sores break out on the prepuce, near the first, and assume all the appearance of chancres.

When, in the treatment of chancres, a bubo arises, while the constitution is under the influence of a sufficient quantity of mercury to cure such sores, which medicine has also been rubbed into the lower extremity, on the same side as the bubo, Mr. Hunter suspects, that the swelling in the groin is not venereal, but is produced by the mercury. In these cases he always preferred conveying mercury into the system in some other manner.

With respect to the treatment of chancres in women, since it is difficult to keep dressings on the parts, Mr. Hunter advises the sores to be frequently washed with some mercurial solution, and, speaks of one, made with oxymuriate of mercury, as perhaps being the best, since it will act as a specific, and stimulant also, when this is requisite. When the chancres, however, are irritable, they are to be treated in the same manner, as similar complaints in men. When the sores extend into the vagina, this passage must be kept from becoming constricted, or closed, by the introduction of lint.

Sometimes, after a chancre and all venereal disease are cured, the prepuce continues thickened and elongated, so that the glans cannot be uncovered. Perhaps, the case is often without remedy. Mr. Hunter, however, very properly recommends trying every possible means, and he informs us, that the steam of warm water, hemlock fomentations, and cinnabar fumigations, are frequently of singular service.

When the thickening and enlargement of the prepuce cannot be removed by applications, all the portion, anterior to the glans penis, may be cut away. (See *Phymosis*.)

Mr. Hunter has very ably explained, that chancres, both in men and women, often acquire, during the treatment, new dispositions, which are of various kinds, some retarding the cure, and leaving the parts in an indolent thickened state, after

the cure is accomplished. In other instances, a new disposition arises, which utterly prevents the parts from healing, and often produces a much worse disease, than that, from which it originated: Such new dispositions may lead to the growth of tumours. They are more frequent in men, than women, and generally occur only when the inflammation has been violent from some peculiarity of the parts, or constitution. They have sometimes been considered as cancerous.

Among the diseases in question, Mr. Hunter notices those continued, and often increased inflammations, suppurations, and ulcerations, which become diffused through the whole prepuce, and, also, along the common skin of the penis, which becomes of a purple hue, attended with such a general thickening of the cellular membrane, as makes the whole organ appear considerably enlarged. The same writer observes, that the ulceration on the inside of the prepuce will sometimes increase, and run between the skin and the body of the penis, and eat holes through in different places, till the whole is reduced to a number of ragged sores. The glans often share the same fate, till more, or less of it is gone. Frequently, the urethra in this situation is wholly destroyed by ulceration, and the urine is discharged some way farther back. The ulceration, if unchecked, at length destroys all the parts. In this acute case, prompt relief is demanded; but, often the proper mode of treatment cannot be at once determined, owing to our ignorance, in respect to the exact nature of the peculiar cause of the disease. Mr. Hunter states, that the decoction of sarsaparilla is often of service, when given in large quantities, and that he has known the German diet drink effect a cure, after every other remedy had failed. The following diet drinks, he says, have been much recommended.

Take of crude antimony and pumice-stone, pulverized, and tied up in a bit of rag, of each one ounce; China root, sliced, sarsaparilla root, sliced and bruised, of each half an ounce; ten walnuts with their rinds bruised; spring-water, four pints; boiled to half that quantity; filter it, and let it be drunk daily in divided doses.

Take of sarsaparilla, Saunders-wood, white and red, of each three ounces; liquorice and mezereon, of each half an ounce; of lignum rhodium, guaiacum, sassafras, of each an ounce; crude antimony, two ounces; mix them and infuse them in boiling water, ten pints, for twenty-four hours; and, afterwards boil them to five pints, of which let the dose be from a pint and a half to four pints a day.

Mr. Hunter also states, that the extract of hemlock is sometimes of service, and that he has known sea-bathing effect a perfect cure.

Sometimes, when such sores are healing, it becomes necessary to keep the orifice of the urethra from closing, by the introduction of a bougie.

Sometimes, after a chancre has healed, the cicatrix breaks out again, and puts on the appearances of the preceding sore. Occasionally, similar diseases break out in different places from that of the cicatrix. Mr. Hunter represents, that they differ from a chancre in generally not spreading so fast, nor so far; in not being so painful, nor so much inflamed; in not having such hard bases, as venereal sores have; and in not producing buboes. This writer was of opinion, that they were not venereal. They are very apt to recur.

Mr. Hunter does not specify any particular mode of cure for all these cases; but, he mentions one instance, which seemed to be cured by giving forty drops of the lixivium saponarium, every evening and morning, in a basin of broth; and he adverts to another case, which was permanently cured by sea-bathing.

In some instances, after a chancre has healed, the parts, as Mr. Hunter remarks, do not ulcerate; but, appear to become thickened, and indurated. Both the glans and prepuce seem to swell, so as to form on the end of the penis a tumour, or excrescence, shaped very much like a cauliflower, and, when cut into, shewing radii, running from its base, or origin, towards the external surface. It is extremely indolent. It is not always a consequence of the venereal disease; for, Mr. Hunter has seen it arise spontaneously.

No medicine seems to be at all likely to cure the disease: the only successful means is to amputate a considerable part of the penis, and then to keep a proper catheter introduced into the urethra.

WARTS.

Another disposition, induced by the previous occurrence of chancres, is a disposition to form excrescences, or cutaneous tumours, called warts. These are considered by many not simply as a consequence of the venereal poison; but, as possessed of its specific disposition, and, therefore, says Mr. Hunter, they have recourse to mercury for the cure of them; and, it is said, that such treatment often removes them. This eminent practitioner never saw mercury produce this effect, although the medicine was given in sufficient quantity to cure recent chancres, and a lues venerea, in the same person.

Mr. Hunter observes, that as these sub-

stances are excrescences from the body, they are not to be considered as truly a part of the animal, not being endowed with the common, or natural animal powers. Many trifling circumstances make them decay. An inflammation of the sound parts round the wart, or stimuli applied to its surface, will often make it die. Electricity will also induce an action in such excrescences, which they are not able to support; an inflammation is excited round them, and they drop off.

From this account, we must perceive, according to Mr. Hunter, that the knife and escharotics are not always necessary, although, these modes will act more quickly, than any other, especially, when the neck of the wart is small. When such is the form of the excrescence, perhaps, a pair of scissars is the best instrument; but, says the above distinguished writer, when cutting instruments of any kind are horrible to the patient, a silk-thread, tied round the neck of the wart, will do very well. However, whichever plan is adopted, it is in general necessary to touch with caustic the base of the little tumour, after this has separated.

Mr. Hunter remarks, that escharotics act upon warts in two different ways, namely, by deadening a part, and stimulating the remainder, so that, by the application of escharotic, after escharotic, the whole excrescence decays moderately fast; and it is seldom necessary to destroy it down to the very root, which is often thrown off. This, however, is not always the case, and the wart grows again, in which circumstance, it is proper to let the caustic destroy even the root itself.

The potassa cum calce, nitrate of silver, and sulphate of copper, are all proper applications. But, one of the best stimulants is the *æruugo æris* and powder of savin leaves, mixed together. (*Hunter on the Venereal Disease.*)

BUBOES.

The immediate consequence of a chancre, which is called a bubo, and also the remote effects, implied by the term, *lues venerea*, arise from the absorption of recent venereal matter from some surface, where it has either been applied or formed.

We are already aware, that Mr. Hunter believed the matter of gonorrhœa capable of communicating the venereal disease. Hence, he explains in the following terms, the three ways, in which he thought a bubo might arise in consequence of absorption. He observes, that the first and most simple manner, is when the matter, either of a gonorrhœa, or chancre, has only been applied to some

sound surface, without having produced any local effect on the part; but, has been absorbed, immediately after its application. Mr. Hunter affirms, that he has seen instances of this kind, though he confesses they are very rare, and, that, in most cases apparently of this nature, a small chancre may be found to have existed.

The second mode of absorption, or that taking place in a gonorrhœa, Mr. Hunter represents as more frequent.

The third mode is the absorption of matter from an ulcer, which may either be a chancre, or a bubo. This mode is by far the most common, and it proves, with many other circumstances, that a sore, or ulcer, is the most favourable for absorption. Mr. Hunter believed, that absorption was more apt to take place from sores on the prepuce, than those on the glans, and he says, he had seen more buboes from chancres in the first situation.

A fourth mode of absorption from a wound is also an occasional occurrence.

Mr. Hunter notices, that, what is now commonly understood by a bubo, is a swelling, taking place in the absorbing system, especially in the glands, arising from the absorption of some poison, or other irritating matter. When such swellings take place in the groin, they are called buboes, whether they proceed from absorption, or not.

Mr. Hunter regards every abscess in the absorbing system as a bubo, whether in the vessels, or the glands, when the complaint originates from the absorption of venereal matter.

The matter is taken up by the absorbent vessels, and is conveyed by them into the circulation. In its passage through these vessels, it often affects them with the specific inflammation. The consequence is the formation of buboes, which are venereal abscesses. These are exactly similar to a chancre in their nature and effects, the only difference being in regard to size. As the lymphatic vessels and glands are irritated by the specific matter, before it has undergone any change in its passage, the inflammation produced, and the matter secreted, partake of the specific quality.

Inflammation of the absorbent vessels themselves is not nearly so frequent, as that of the glands. In men, such inflammations, in consequence of chancres upon the glans, or prepuce, generally appear, like a cord, leading along the back of the penis from the sores. Sometimes, the absorbents inflame, in consequence of the thickening and excoriation of the prepuce in gonorrhœa. The indurated lymphatics often terminate insensibly near the root of the penis, or near the pubes; while,

in other instances, they extend further to a lymphatic gland in the groin. Mr. Hunter believed, that this affection of the absorbent vessels is truly venereal. The formation of a hard cord, the same author conceived, arose from a thickening of the coats of the absorbents, and from an extravasation of coagulable lymph on their inner surface.

A cord, of the above kind, often suppurates, sometimes in more places, than one, so as to form one, two, or three buboes, or small abscesses in the body of the penis.

Inflammation much more frequently affects the absorbent glands, than the vessels. The structure of the former parts appear to consist of the ramifications and reunion of the absorbent vessels. From this structure, observes Mr. Hunter, we may reasonably suppose, that the fluid absorbed is in some measure detained in these glands, and thus has a greater opportunity of communicating the disease to them, than to the distinct vessels.

Swellings of the absorbent glands may originate from other diseases, and such should be carefully discriminated from those which arise from the venereal poison. With this view, Mr. Hunter advises us first to enquire into the cause, in order to ascertain, whether there is any venereal complaint at some greater distance from the heart, such as chancres on the penis, or any preceding disease in this situation. He recommends us to enquire, whether any mercurial ointment has been at all applied to the leg and thigh on the diseased side; for, mercury applied to those parts for the cure of a chancre, will sometimes cause glandular enlargements, which are occasionally mistaken for venereal buboes. This irritation of the inguinal glands by the mechanical action of mercurial ointment, has been particularly noticed by Professor Assalini, who states, that he has had frequent opportunities of convincing himself of the fact. (See *Manuale di Chirurgia*, p. 67.) Mr. Hunter also reminds us to observe, whether there has been any preceding disease in the constitution, such as a cold, fever, &c. The quick, or slow, progress of the swelling, is likewise to be marked, and the tumour must be distinguished from femoral hernia, lumbar abscesses, and aneurisms of the crural artery.

Sometimes, the venereal matter does not produce its effects on the absorbent glands, for some time after absorption has taken place. In certain instances, Mr. Hunter notices, that, at least, six days have elapsed; a circumstance, which could only be known by the chancres having been healed six days before the bubo began to appear. However, Mr. Hunter infers, that the matter had been much

longer absorbed, as the last matter of a chancre is probably not venereal.

Mr. Hunter next remarks, that the glands, nearest to the seat of absorption, are in general the only ones, which are attacked. Thus, when the matter has been taken up from the penis in men, the inguinal glands are affected; and, when from the vulva in women, those glands swell, which are situated between the labia and thigh, and the round ligaments.

It was one of Mr. Hunter's opinions, that only one gland at a time is commonly affected by the absorption of venereal matter. If this sentiment be correct, the circumstance may be considered as a kind of criterion between venereal and other buboes. The second order of lymphatic vessels and glands are never affected; as, for instance, those along the iliac vessels, or back. Mr. Hunter informs us, that he also observed, that, when the disease was contracted by a sore, or cut upon the finger, the bubo occurred a little above the bend of the arm, by the side of the biceps muscle, and no swelling of this sort formed in the arm-pit. However, he mentions his having heard of a few rare cases, in which a swelling in the axilla was also produced.

When buboes arise from a venereal disease on the penis, they are situated in the glands of the groin. When a bubo arises from a gonorrhœa, either groin may be attacked. But when the disease originates from a chancre, the bubo most frequently takes place in the nearest groin.

The situation of the absorbent glands, however, is not always exactly the same, and the course of the lymphatics therefore is subject to some variety. Hence, Mr. Hunter has seen a venereal bubo, produced by a chancre on the penis, situated a considerable way down the thigh; he has also often seen buboes as high as the lower part of the belly, before Poupart's ligament; and sometimes near the pubes.

BUBOES IN WOMEN.

The seat of absorption is more extensive in the female sex, and the course of some of the absorbents is also different. Hence, buboes in women may occur in three situations, two of which are totally different from those in men.

When chancres are situated forwards, near the meatus urinarius, nymphæ, clitoris, labia, or mons veneris, the absorbed matter is generally conveyed along one, or both of the round ligaments, and the buboes are formed in those ligaments, just before they enter the abdomen. Mr. Hunter suspected such buboes not to be glandular ones; but, only inflamed absorbents.

When chancres are situated far back, near, or on the perinæum, the absorbed matter is carried forward along the angle, between the labium and the thigh, to the glands in the groin, and often, in this course, small buboes are formed in the absorbents, similar to those abscesses, which occur on the penis in men.

When the effects of the poison do not rest here, a bubo in the groin may be occasioned, in the same manner as in men.

It is more difficult to learn, whether a bubo is venereal in women, than men, owing to the frequent difficulty of ascertaining, that there is no infection present. In men, who have had no local complaint, the bubo can only be venereal, when direct absorption from the surface of the skin has taken place.

MANNER IN WHICH BUBOES MAKE THEIR APPEARANCE, &c.

A bubo, says Mr. Hunter, commonly begins with a sense of pain, which leads the patient to examine the part, where a small hard tumour is to be felt. This increases, like every other inflammation, that has a tendency to suppuration, and, unless checked, pus forms, and ulceration follows, the matter making its way to the skin very fast.

The above celebrated writer remarks, however, that there are some cases, which are slow in their progress. This circumstance he imputes either to the inflammatory process being kept back by mercury, or other means, or to its being retarded by a scrophulous tendency.

The inflammation, he says, is at first confined to the gland, which may be moved about in the cellular membrane; but, when the part has become enlarged, or when the inflammation, and suppuration, are more advanced, the surrounding parts become more inflamed, and the tumour is more diffused. Some buboes become complicated with an erysipelatous and œdematous affection, by which means, they are rendered more diffused, and less disposed to suppurate.

Mr. Hunter allows, that to distinguish, with certainty, the true venereal bubo from swellings of the glands in the groin, may be very difficult. He represents the true venereal bubo, in consequence of a chancre, as being most commonly confined to one gland. It preserves its specific distance till suppuration has taken place, and then becomes more diffused. It is rapid in its progress from inflammation to suppuration and ulceration. The suppuration is commonly large, considering the size of the gland, and there is only one abscess. The pain is very acute, and the inflamed part of the skin is of a florid red colour.

Mr. Hunter describes such buboes, as arise without any visible cause, as being of two kinds. One sort inflame and suppurate briskly. These he always suspected to be venereal, although he allows, there was no proof of it, and only a presumption deduced from the quick progress of the disease.

The second kind are generally preceded, and attended with slight fever, or the common symptoms of a cold, and they are generally indolent and slow in their progress. If they are quicker, than ordinary, they become more diffused, than venereal buboes, and they are often not confined to one gland. When very slow, they give but little sensation; but, when quicker, the sensation is more acute, though not so much so as in venereal cases. They usually do not suppurate, and often become stationary. When they do suppurate, it is in a slow manner, and, frequently, in more glands, than one, while the inflammation is more diffused, and not considerable, in relation to the swelling. The matter makes its way to the skin slowly, and the part affected is of a more purple colour. Sometimes, the abscesses are very large, yet not painful.

In considering whether the swellings of the inguinal glands are, or are not venereal, the first thing to be attended to is, whether, or not, there are any venereal complaints. If there are none, Mr. Hunter observes, that there is a strong presumptive proof, that the swellings are not venereal. When the swelling is only in one gland, very slow in its progress, and gives but little, or no pain, it is probably merely scrophulous. However, when the swelling is considerable, diffused, and attended with some inflammation and pain, the constitution is most probably affected with slight fever, the symptoms of which are lassitude, loss of appetite, want of sleep, small quick pulse, and an appearance of approaching hectic. Such swellings are long in getting well, and do not seem to be affected by mercury, even when very early applied.

Mr. Hunter mentions his having seen the above affection of the groin, together with the constitutional indisposition, take place, where there were chancres; and he was puzzled to determine, whether the disease in the groin was sympathetic, from derangement of the constitution, or whether it arose from the absorption of matter. He had long suspected, that there was a mixed case, and was at last certain, that such a case might prevail. He says, he has seen instances, in which the venereal matter, like a cold, or fever, only irritated the glands to disease, producing in them scrophula, to which they were disposed.

In such cases, says Mr. Hunter, the swellings commonly arise slowly, give but little pain, and seem to be rather hastened

in their progress, if mercury is given to destroy the venereal disposition. Some suppurate while under this resolving course; and others, which probably had a venereal taint at first, become so indolent, that mercury has no effect upon them, and, in the end, they either get well of themselves, or by other means.

According to Mr. Hunter, buboes are undoubtedly local complaints.

TREATMENT OF BUBOES.

When a bubo is certainly a venereal one, and only in an inflamed state, an attempt is to be made to resolve the swelling. The propriety of the attempt, however, depends on the progress, which the disease has made. If the bubo be very large, and suppuration appears to be near at hand, resolution is not likely to be effected. When suppuration has already taken place, Mr. Hunter much doubted the probability of any success attending the endeavour, which now might possibly only retard the suppuration, and protract the cure.

The resolution of these inflammations, says Mr. Hunter, depends principally on mercury, and almost absolutely on the quantity, which can be made to pass through them. When suppuration has taken place, the cure also depends on the same circumstances.

The quantity of mercury, which can be made to pass through a bubo, is represented by Mr. Hunter, as depending principally on the quantity of external surface for absorption beyond the bubo.

The mercury is to be applied to such surfaces, as allow the remedy, when absorbed, to pass through the diseased gland. In this manner, the disease in the groin is subdued, and the constitution is less liable to be contaminated.

However, Mr. Hunter accurately notices, that the situation of many buboes is such, as not to have much surface for absorption beyond them; for instance, the buboes on the body of the penis, arising from chancres on the glans, or prepuce.

When the bubo is in the groin, Mr. Hunter recommends surgeons to pay attention to whether the swelling is in the upper part of the thigh and groin, on the lower part of the belly before Poupart's ligament, or near the pubes. When the buboes are situated on the body of the penis, the absorbents, leading directly from the seat of absorption, are themselves diseased. When the bubo is in the groin, and, at the upper part of the thigh, we may conclude, that the lymphatics, both from the penis and thigh, run to the affected gland. When the bubo is high up, or on the lower part of the belly, before Poupart's ligament, probably, the absorbents, which arise from about the groin,

lower part of the belly and pubes, pass through the bubo. When the bubo is far forward, the absorbents of the penis and skin about the pubes, pass through the swelling. Mr. Hunter contends, that the knowledge of these circumstances is very necessary, in order to apply mercury in the most advantageous situations.

The utility of rubbing the mercury into surfaces, the absorbents of which lead through the bubo, must be obvious, when it is considered, that the medicine cannot pass to the common circulation, without going through the diseased parts; that it must promote the cure, as it passes through them; and that it also prevents the matter, which has already passed, and is still continuing to pass, into the constitution, from acting there. Thus the bubo is cured, and the constitution, at the same time, preserved.

Mercury alone, however, is not always capable of effecting the cure of buboes.

When the inflammation rises very high, bleeding, purging, and fomenting, are generally recommended. When the inflammation was erysipelatous, Mr. Hunter had a high opinion of bark; and, when it was scrophulous, he used to recommend hemlock, and poultices made with seawater.

The same eminent writer also takes notice of the fact of emetics sometimes occasioning the absorption of buboes, even after they contain matter.

1. *Resolution of the Inflammation of the Absorbents on the Penis.*

Though there is not surface enough beyond the bubo, for rubbing in a sufficient quantity of mercury, to prevent the effects of absorption, Mr. Hunter still advises this surface to be kept constantly covered with mercurial ointment. In consequence of the surface in question being so small, more mercury must also be conveyed into the system by the mouth, or frictions on some other part. Mr. Hunter observes, that this is necessary, both in order to prevent a lues venerea, and to cure the parts themselves. The quantity of mercury must be regulated by the appearances of the original complaint, and the readiness, with which the disease gives way. The same method, he adds, is to be followed in women, and the ointment should be kept continually applied to the inside and outside of the labia.

2. *Resolution of Buboes in the Groin.*

The inflammation of the absorbent glands, is to be treated on the same principle as that of the vessels. In the first case, however, we are able to make a larger quantity of mercury pass through the diseased parts. When the bubo is in the groin, the mercurial ointment is to be rubbed on the thigh. This surface, as Mr.

Hunter remarks, will in general absorb as much mercury as will be sufficient to resolve the bubo, and preserve the constitution from being contaminated; but, when resolution does not readily take place, the same author advises us to increase the surface of friction, by rubbing the ointment upon the leg.

When the bubo is on the lower part of the belly, the ointment should be rubbed also on the penis, scrotum, and belly. The same plan should be followed when the bubo is still more forward.

Mr. Hunter states, that when the bubo gives way, the mercurial frictions must be continued, till it has entirely subsided, and, perhaps, longer, on account of the chancre, which may not yield so soon as the bubo. After the bubo has supplicated, Mr. Hunter is doubtful, whether rubbing in mercury is useful, or not.

3. Resolution of Buboes in Women.

When the swellings are situated between the labia and thigh, Mr. Hunter recommends the mercurial ointment to be rubbed in all about the anus and buttock, from which parts the absorbents probably run through the seat of the diseases. When the buboes are in the round ligaments, the surface for absorption will not be large enough, and more mercury must be internally given, or rubbed into other surfaces.

When the bubo is in one of the inguinal glands, the same plan is to be adopted, as in the same case in men.

4. Buboes in unusual Situations.

When buboes form in the arm, or arm-pit, in consequence of the absorption of venereal matter from wounds on the hands, or fingers, mercurial ointment should be rubbed on the arm and fore-arm. Mr. Hunter adds, however, that this surface may not be sufficient, so that it may be proper to convey more mercury into the system in other ways. He states, that he has seen a true venereal chancre on the middle of the lower lip, attended with a bubo, on each side of the neck, under the lower jaw, close to the maxillary gland. The swellings were resolved by applying mercurial ointment to them, and the chin, and lower lip.

5. Quantity of Mercury necessary for the Resolution of a Bubo.

Mr. Hunter observes, that the quantity of mercury, necessary for the resolution of a bubo, must be proportioned to the obstinacy of the complaint; but, that care must be taken not to extend the employment of the medicine so far as to produce certain effects on the constitution. When the bubo is in a situation, which admits of a large quantity of mercury being rubbed in, so as

to pass through the swelling, and when the complaint readily yields to the use of half a drachm of mercurial ointment, every night, the mouth not becoming sore, or at most, only tender, the above author thinks it sufficient to pursue this course, till the gland is reduced to its natural size. In this manner, the constitution will probably be safe, provided the chancre, which may have caused the bubo, heals at the same time. When the mouth is not affected in six, or eight days, and the gland does not readily resolve, then two scruples, or a drachm, may be applied every night; and, continues Mr. Hunter, if there should still be no amendment, even more must be rubbed in. In short (says he) if the reduction is obstinate, the mercury must be pushed as far as can be done without a salivation.

When there is a bubo on each side, so much mercury cannot be made to pass through each, as the constitution in general will not bear this method. However, Mr. Hunter sanctions the plan of minding the soreness of the mouth less in this kind of case; though, he adds, that it is better to let the buboes proceed to suppuration, than to load the system with too much mercury.

When the situation of buboes will not allow an adequate quantity of absorbed mercury to pass through them, the frictions must be continued in order to affect the constitution; but, according to Mr. Hunter, more mercury in this case will be requisite, than when the remedy can be made to pass directly through the diseased gland.

Many buboes remain swollen, without either coming to resolution, or suppuration; and, notwithstanding every attempt to promote these changes, the glands become hard and scirrhus. Mr. Hunter conceived, that cases of this sort are either scrophulous at first, or become so as soon as the venereal disposition is removed. He advises the use of hemlock, sea-water, poultices, and sea-bathing.

According to a modern surgeon, at Milan, a gentleman of judgment and considerable experience, when buboes are in a chronic stationary state, the application of blisters to the swelling is attended with the most beneficial effects. And, he rightly observes, that, when such tumours are extremely hard and indolent, it is more advantageous to let the patient have the benefit of the open air, exercise, and his accustomed mode of living, than to confine him in an hospital. (*Assalini, in Manuale di Chirurgia, p. 64; Milano, 1812.*)

6. Treatment of Buboes which suppurate.

The suppuration of buboes frequently cannot be prevented by any known means. They are then to be treated, in some re-

spects, like any other abscess. Before opening buboes, Mr. Hunter conceived it was advantageous to let the skin become as thin as possible, as a large opening would then become unnecessary, and no measures would be requisite for keeping the skin from closing, before the bottom of the sore had healed.

Mr. Hunter thinks it doubtful whether the application of mercury should be continued through the whole suppuration. He was inclined to continue it; but, in a smaller quantity.

There has been much dispute, whether a bubo should be opened, or allowed to burst of itself, and whether the opening should be made with a cutting instrument, or caustic. On this subject, Mr. Hunter remarks, that there is no peculiarity in a venereal abscess to make one practice more eligible, than another. The surgeon, he says, should in some degree be guided by the patient. Some patients are afraid of caustics; others, of cutting instruments. But, when the surgeon has the choice, Mr. Hunter expresses a preference to opening the bubo with a lancet, in which method, no skin is lost. But he observes, that when a bubo is very large, and there will be a great deal of loose skin, after the discharge of the matter, he thinks, that caustic may, perhaps, be better, as it will destroy some of the redundant skin, and occasion less inflammation, than what is caused by an incision. The potassa cum calce is the caustic commonly employed.

After the bubo has been opened, surgeons usually poultice it, as long as the discharge and inflammation are considerable, and then they employ dressings, which must be of such a quality, as numerous undescribable circumstances may indicate. The use of mercury, in the mean while, is to be continued, both to make the bubo heal, and prevent the bad effects, which might otherwise arise from the matter being continually absorbed. The mercury should also be rubbed in, so as to pass, if possible, through the diseased groin.

The mercurial course is to be pursued, till the sore is no longer venereal. But, in general, since this point is difficult to ascertain, the mercury must be given till the part has healed, and even somewhat longer, when the bubo has healed very quickly; for, the constitution is afterwards very apt to become contaminated.

However, mercury is not to be continued thus long in all cases; for, as Mr. Hunter explains, buboes often assume, besides the venereal, other dispositions, which mercury cannot cure; but, will even exasperate.

CONSEQUENCES OF BUBOES.

Sometimes the sores, when they are

losing, or entirely deprived of the venereal disposition, become changed into ulcers of another kind, and, most probably of various kinds. How far it is a disease arising from a venereal taint, and the effects of a mercurial course jointly, says Mr. Hunter, is not certain. This writer suspected, however, that the nature of the part, or constitution, had a principal share in the malady.

Mr. Hunter observes, that such diseases make the cure of the venereal affection much more uncertain, because, when the sore becomes stationary, or the mercury begins to disagree, we are ready to suspect, that the virus is gone; but, this is not always the case. Perhaps, the action of the venereal poison is only suspended, and will commence again, as soon as the other disease ceases.

In these cases, Mr. Hunter recommends attacking the predominant disease; but, he allows that there is difficulty in ascertaining its nature, and finding out, whether it is venereal, or not.

The same author also acquaints us, that he has seen some buboes exceedingly painful and tender to almost every thing, that touched them, and the more mild the dressings were, the more painful the parts became.

In some instances, the skin only seems to become diseased. The ulceration spreads to the surrounding integuments, while a new skin forms in the centre, and keeps pace with the ulceration, so that an irregular sore, which Mr. Hunter compares with a worm-eaten groove, is formed all round. It appears only to have the power of contaminating the parts, which have not yet been affected; and those, which have, readily heal.

When buboes become stationary, and seem little inclined to spread, attended with a sinus, or two, hemlock, joined with bark, is, according to Mr. Hunter, the medicine most frequently serviceable. It is best to use it both externally and internally. The same author also speaks favourably of sarsaparilla, sea-bathing, and sea-water poultices. He states, that at the Lock Hospital, gold refiners' water has been found a useful application; that, in some cases, drinking large quantities of orange-juice, and in others taking meze-reon, have been found serviceable.

LUES VENEREA.

Surgeons imply, that a *lues venerea* has taken place, when the venereal virus has been absorbed into the circulation. Mr. Hunter does not think the epithet *constitutional* strictly proper in its application to this form of the venereal disease. By *constitutional* disease, he observes, he should understand that, in which every part of

the body is acting in one way, as in fevers of all kinds; but, the venereal poison seems to be only diffused through the circulating fluids, and, as it were, to force certain parts of the body to assume the venereal action, which action is perfectly local. To use Mr. Hunter's phrase, it takes place in different parts in a regular succession of susceptibilities. Only a few parts are acting at the same time; and a person may be constitutionally affected in this way, and yet almost every function may be perfect.

The venereal poison is generally conveyed into the system from a chancre. It may, also, according to Mr. Hunter's doctrine, be absorbed from a gonorrhœa. There is likewise a possibility of its getting into the circulation from the surface of the body, without any previous ulceration. It may be absorbed from common ulcers, without necessarily rendering these venereal; and it may be taken up from wounds, in which cases, it in general induces a previous ulceration in the wound.

VENEREAL ULCERS.

In consequence of the blood being contaminated with real venereal pus, it might be expected, that the local effects, thus produced, would be similar in their nature to those, producing them. Mr. Hunter believed, that this is not the case. He notices, that the local effects, from a constitutional contamination, are all of one kind, viz. ulcers, let the effects make their appearance on any surface whatever, either the throat, or common skin. But, Mr. Hunter conceived, that if the matter, when in the constitution, were to act upon the same specific principles, as that, which is externally applied, a gonorrhœa would arise, when it affected a canal, and, only sores, or chancres, when it attacked other surfaces.

Mr. Hunter found, that even the sores, which are caused in the throat, are very different from chancres. He says, that the true chancre produces considerable inflammation, often attended with a great deal of pain, and quickly followed by suppuration. But, the local effects, arising from the virus in the constitution, are slow in their progress, attended with little inflammation, and are seldom or never painful, except in particular parts. However, Mr. Hunter allows, that this sluggishness in the effects of the poison depends on the nature of the parts diseased; and, he owns, that when the tonsils, uvula, or nose, are affected, the progress of the morbid mischief is rapid, and bears a greater resemblance to a chancre, than when it occurs on the skin. Even in those parts Mr. Hunter thought, that the ulcers were attended with less inflammation, than

chancres, which were spreading with equal celerity.

The matter, secreted by such sores, as arise from a constitutional contamination, was always considered, before the time of Mr. Hunter, as being of a poisonous quality, like the matter of a chancre. At first, one would certainly expect, that this was actually the case, because venereal matter is the cause, and mercury cures chancres, and also ulcers proceeding from a lues venerea. Mr. Hunter remarks, however, that the latter circumstance is not a decisive proof, since mercury is capable of curing many diseases, besides the venereal. He also takes notice, that when pus is absorbed from a chancre, it generally produces a bubo; but, that a bubo is never occasioned by the absorption of matter from a venereal sore, arising from the virus diffused in the circulation. For instance, when there is a venereal ulcer in the throat, no buboes occur in the glands of the neck; when there are syphilitic sores on the arms, or even suppurating nodes on the ulna, no swellings form in the glands of the arm-pit, although these complaints occur, when fresh venereal matter is applied to a common sore on the arm, hand, or fingers. No swelling is produced in the groin, in consequence of nodes, or blotches on the legs and thighs.

Some very important experiments are related in Mr. Hunter's Treatise on the Venereal Disease, in order to shew, that the matter from a gonorrhœa, or chancre, is capable of affecting a man locally, who has already got a lues venerea, and that the matter from secondary syphilitic sores has not the same power. The particulars, however, are too long to be inserted in this book.

PARTS MOST SUSCEPTIBLE OF THE LUES VENEREA, &c.

Some parts of the body seem to be much less susceptible of the lues venerea, than others; indeed, Mr. Hunter observes, that, as far as our knowledge extends, certain parts cannot be affected at all. The brain, heart, stomach, liver, kidneys, and several other viscera, have never been known to be attacked by the lues venerea.

The *first order of parts*, or those, which become affected in the early stage of the lues venerea, are the skin, tonsils, nose, throat, inside of the mouth, and sometimes the tongue.

The *second order of parts*, or those, which are affected at a later period, are the periosteum, fasciæ, and bones.

Mr. Hunter conceived, that one great reason of the superficial parts of the body suffering the effects of the lues venerea sooner than the deep-seated ones, depend-

ed on the former being more exposed to external cold. Even the second order of parts do not all become diseased at the same time, nor every where at once. But, on the contrary, it is observed, that, those, which are nearest the external surface of the body, are first diseased, as, for instance, the periosteum, bones of the head, the tibia, ulna, bones of the nose, &c. Neither does the disease affect these bones on all sides equally; but, first on that side, which is next to the external surface. Mr. Hunter notices, however, that the susceptibility of particular bones does not altogether depend on their nearness to the skin; but, on this circumstance, and their hardness together.

After many ingenious observations, Mr. Hunter presents the reader of his treatise with the following summary of his doctrines of the lues venerea.

First; that most parts, if not all, that are affected in the lues venerea, are affected with the venereal irritation at the same time.

Secondly; that the parts, exposed to cold, are the first which admit the venereal action; then the deeper-seated parts according to their susceptibility for such action.

Thirdly; that the venereal disposition, when once formed in a part, must necessarily go on to form the venereal action.

Fourthly; that all parts of the body, under such disposition, do not run into action equally fast, some requiring six or eight weeks; others, as many months.

Fifthly; in the parts, which first come into action, the disease continues to increase, without wearing itself out; while those, which are second in time, follow the same course.

Sixthly; mercury hinders a disposition from forming, or, in other words, prevents contamination.

Seventhly; mercury does not destroy a disposition already formed.

Eighthly; mercury hinders the action from taking place, although the disposition be formed.

Ninthly; mercury cures the action.

On these principles, Mr. Hunter asserts, that the cure of the disease may be easily explained.

SYMPTOMS OF LUES VENEREA.

Mr. Hunter remarks, that the time, necessary for the appearance, or production of the local effects, in parts most susceptible of the disease, after the virus has got into the constitution, is uncertain; but, he says, in general, it is about six weeks; in many cases, the period is much longer; in other instances, it is shorter. Sometimes, the local effects make their

appearance within a fortnight after the possibility of absorption.

The effects, on other parts of the body, which are less susceptible of the venereal irritation, or slower in their action, are of course much later in making their appearance. Mr. Hunter also notices, that when the first and second order of parts are both contaminated, the effects, generally, do not begin to appear in the latter, till after a considerable time, and sometimes, not till those affecting the former parts have been cured.

Mr. Hunter, however, mentions his having seen instances, in which the periosteum, or bone, has been affected before any of the first order of parts: but, he was uncertain, whether the skin, or throat, would afterwards have become diseased, as the disorder was not allowed to go on.

In the first order of parts, most susceptible of the effects of lues venerea, the disease is much quicker in its progress, than in the second order of parts. Mr. Hunter represents, that the symptoms in each succeeding part, which becomes affected, are slower and slower in their progress, and of a more fixed kind. It was also an observation, made by the same ingenious writer, that similar parts come sooner into action, and appear to go on more rapidly with it, in proportion as they are nearer the source of the circulation. The disease appears earlier on the face, head, shoulders, and breast, and the eruptions suppurate sooner than on the legs.

SYMPTOMS OF THE FIRST STAGE OF THE LUES VENEREA.

According to Mr. Hunter, the first symptoms of the disease, after absorption, appear either on the skin, or in the throat, or mouth.

VENEREAL ERUPTIONS.

Mr. Hunter thought, that these generally occurred all over the body. It is accurately observed, however, by Dr. Bateman, that syphilitic affections of the skin commonly make their first appearance on the face, where they are usually copious, and on the hands and wrists. (*Pract. Synopsis of Cutaneous Diseases*, p. 332, edit. 3.) It is also noticed by the same well informed writer, that their colour is in general less livid, than that of ordinary eruptions, being of a brownish red of different shades; but, he states, that this is not universal; for, some of the syphilitic ecthymata have a bright red base in the beginning. Exposure to cold accelerates their progress, and increases their extent; while, on the other hand,

warmth retards and ameliorates them. (*P.* 333.) The discolourations make the skin appear mottled, and many of the eruptions disappear, while others continue, and increase with the disease.

In other cases, the eruption comes on in distinct blotches, which are often not observed, till the scurf has begun to form. At other times, the eruption assumes the appearance of small distinct inflammations, containing matter, and resembling pimples, not being, however, so pyramidal, nor so red at the base. Mr. Hunter also observes, that venereal blotches, on their first coming out, are often attended with inflammation, which gives them a degree of transparency, which is generally greater in the summer, than the winter, especially, if the patient be kept warm. In a little time, this inflammation disappears, and the cuticle peels off in the form of a scurf. The latter occurrence often misleads the patient and the surgeon, who look upon this dying away of the inflammation, as a decay of the disease, till a succession of scurfs undeceives them. Mr. Hunter adds, that the discolourations of the cuticle arise from the venereal irritation, and are to be seldom regarded as a true inflammation, since they rarely have any of its characteristics, such as tumefaction and pain. However, he explains, that in parts, which are well covered, or which are constantly in contact with other parts, there is more of the true inflammatory appearance, especially, about the anus.

The parts affected next begin to alter their appearance, and form a copper-coloured, dry, inelastic cuticle, called a scurf. This is thrown off, and new ones are formed. Mr. Hunter relates, that these appearances spread to the breadth of a sixpence or shilling; but, seldom more extensively, at least, for a considerable time. In the mean while, every succeeding scurf becomes thicker and thicker, till at last it becomes a common scab. Then the disposition for the formation of matter takes place in the cutis underneath, and a true ulcer is produced, which commonly spreads, although in a slow way.

These appearances arise first from the gradual loss of the true sound cuticle, which the diseased cutis cannot reproduce. As a kind of substitute for this want of cuticle, an exudation takes place, and forms a scale. The matter afterwards acquiring more consistence, at last forms a scab. However, before the disease has attained this condition, the cutis has ulcerated, after which the discharge is more like true pus. When this form of the lues venerea attacks the palms of the hands and soles of the feet, where the cuticle is thick, this latter part first becomes sepa-

rated, and peels off. A new one is immediately formed, which also separates. In this manner a series of new cuticles take place, in consequence of scurfs not being so readily formed there as on the common skin. When the disease is confined to the palms of the hands, or soles of the feet, Mr. Hunter mentions, that there is difficulty in determining whether it is venereal, or not; because, most diseases of the cutis, in these situations, produce a separation of the cuticle, attended with the same appearances in all, and having nothing characteristic of the venereal disease.

When the affected part of the skin is opposed by another portion of skin, which keeps it in some degree more moist, as between the nates, about the arms, between the scrotum and the thigh, in the angle between the two thighs, on the red part of the lip, or in the arm-pits, the eruptions, instead of being attended with scurfs and scabs, become accompanied by an elevation of the skin, which is swollen with extravasated lymph into a white, soft, moist, flat surface, which discharges a white matter.

Mr Carlisle has recently pointed out an herpetic abrasion of the cuticle, sometimes on the breast, or abdomen, which looks like venereal blotches. He states, that it is less deep in the skin; that it has less of an inflammatory base; and that it is not so distinctly circumscribed, as the true venereal blotch. It never forms a purulent crust; but, is simply a furfuraceous scaling of the cuticle. He observes, that this form of disease seems to be produced by a disordered stomach and liver. (*See Lon. Med. Reposit. Vol. 7, p. 92.*)

A venereal eruption often attacks that part of the fingers, on which the nail is formed. Here, the disease renders that surface red, which is seen shining through the nail; and, if allowed to continue, a separation of the nail takes place, similar to that of the cuticle in the above cases. However, Mr. Hunter states, that there cannot be the same regular succession of nails, as of cuticles in other instances.

Such surfaces of the body, as are covered with hair, may also be attacked, and the hair separates, and cannot be reproduced as long as the disease lasts.

It must be allowed, that it is frequently very difficult to say, whether an eruption is syphilitic, or not, and an opinion should rather be formed from the history of the case, than from any particular appearance of the eruption itself. As Dr. Bateman has remarked, the cutaneous eruptions, which are the result of the venereal poison, are often the source of considerable embarrassment to the practitioner. They assume such a variety of forms, that they bid defiance to any arrangement founded upon their external character; and, in fact, they possess no common, or exclusive

marks, by which their nature and origin are indicated. There is, perhaps, no order of cutaneous appearances, and scarcely any genus, or species of the chronic eruptions, so admirably described by Dr. Bateman, which these secondary symptoms of syphilis do not occasionally resemble. This gentleman admits, however, that, in many cases, there is a difference, which a practised eye will recognize, between the ordinary diseases of the skin and the syphilitic eruptions, to which the same generic appellation might be given. This, says he, is often observable in the shade of colour, in the situation occupied by the eruption, in the mode of its distribution, and in the general complexion of the patient. Hence, to a person conversant with those ordinary diseases, a degree of anomaly in these respects will immediately excite a suspicion, which will lead him to investigate the history of the progress of such an eruption, and of its concomitant symptoms. (See *Bateman's Practical Synopsis of Cutaneous Diseases*, p. 331—332, edit. 3.)

Considerable light is also often thrown on these doubtful cases, by a review and consideration of the remedies which have been previously administered, and the effects, which they appeared to produce.

For an account of the ordinary chronic eruptions, to which syphilitic affections of the skin are most nearly allied, I must refer the reader to Dr. Bateman's valuable publication.

VENEREAL DISEASE OF THE THROAT, MOUTH, AND TONGUE.

In the throat, tonsils, and inside of the mouth, the disease generally makes its appearance at once in the form of an ulcer, without much previous tumefaction. Consequently, the tonsils are not much enlarged. It is observed by Mr. Hunter, that, the venereal inflammation attacks the surface of these parts, and very soon produces a sore.

A venereal ulcer in the throat should be carefully distinguished from other kinds of sores in the same situation. The syphilitic one is in general tolerably well marked. However, Mr. Hunter confesses, that, it may not in every instance be distinguishable from an ulcer of a different nature. Sores in the throat, which are really venereal, may resemble others which are not so. The same celebrated author mentions, that there are several diseases of this part, which do not produce ulceration on the surface. One of these is common inflammation of the tonsils. The inflamed place often suppurates in the centre, so as to form an abscess, which bursts by a small opening; but, never looks like an ulcer, that has begun upon the surface, like

a true venereal one. The case, just alluded to, is always attended with too much inflammation, pain, and tumefaction, of the parts, to be venereal. Also when it suppurates and bursts, it subsides directly, and it is generally attended with other inflammatory symptoms in the constitution.

Mr. Hunter next takes notice of another disease, consisting of an indolent tumefaction of the tonsils, and peculiar to many persons, whose constitutions are disposed to scrophula. The complaint produces a thickness in the speech. Sometimes coagulable lymph is thrown out on the surface of the parts affected, and occasional appearances, which are by some called ulcers; by some, sloughs; and occasionally, by others, putrid sore-throats. The case is attended with too much swelling to be venereal, and, with a little care, it may easily be distinguished from an ulcer, or loss of substance. However, when this difference is not obvious at first sight, it is proper to endeavour to remove some of the lymph, and, if the surface of the tonsil underneath should appear to be free from ulceration, we may conclude with certainty, that the disease is not venereal. Mr. Hunter states, that he has seen a chink filled with coagulable lymph, so as to appear very much like an ulcer; but, on removing that substance, the tonsil underneath was found perfectly sound. He adds, that he has seen cases of a swelled tonsil, having a slough in its centre, which slough, before its detachment, looked very like a foul ulcer. The stage of the complaint, he says, is even more puzzling, when the slough has come out; for, then the disease has most of the characters of the venereal ulcer. Whenever he met with the disease in its first stage, he always treated it, as if it had been of the nature of erysipelas, or a carbuncle. When the complaint is in its second stage, without any preceding local symptoms, he recommends the practitioner to suspend his judgment, and to wait a little, in order to see how far nature is able to relieve herself. If there should have been any preceding fever, the case is still less likely to be venereal. Mr. Hunter informs us, that he has seen a sore-throat of this kind mistaken for venereal, and mercury given, till it affected the mouth, when the medicine brought on a mortification of all the parts concerned in the first disease.

Another complaint of these parts, which Mr. Hunter represents as being often taken for a venereal one, is an ulcerous excoriation, which runs along their surface, becoming very broad and sometimes foul, having a regular termination, but, never going deeply into the substance of the parts, as the venereal ulcer does. No part of the inside of the mouth is exempted from this ulcerous excoriation; but, Mr. Hunter thought that the disease most frequently occurred about

the root of the uvula, and spread forwards along the palatum molle. He remarks, that the complaint is evidently not venereal, since it does not yield to mercury. He has seen these ulcerous excoriations continue for weeks, without undergoing any change, and a true venereal ulcer make its appearance on the surface of the excoriated part. He says, that the excoriations in question have been cured by bark, after the end of the mercurial course, which cured the syphilitic sore.

This author describes the true venereal ulcer in the throat, as a fair loss of substance, part being dug out, as it were, from the body of the tonsil; it has a determined edge, and is commonly very foul, having thick white matter, like a slough, adhering to it, and not admitting of being washed away. Ulcers in such situations are always kept in a moist state, and the matter cannot dry and form scabs, as it does on sores upon the skin. The ulcer is also much more rapid in its progress, and generally has thickened edges.

When lues venerea attacks the tongue, it sometimes produces a thickening and hardening of the part. However, it also frequently gives rise to ulceration, as in other parts of the mouth.

Venereal sores on the tongue, are generally more painful, than those on the skin; but, less so, than common sore-throats from inflamed tonsils. They oblige the patient to speak thick, as if his tongue were too large for his mouth, with a small degree of snuffing.

Mr Hunter doubted the reality of a venereal ophthalmy, though he owns there are inflammations of the eyes, which yield to mercury. The case commonly supposed to be venereal, is described in the article *Ophthalmy*.

SYMPTOMS OF THE SECOND STAGE OF THE LUES VENEREA.

The second order of parts, or those, which are commonly affected at a later period, may occasionally assume the venereal action, before the disease has produced its local effects on the first order of parts; and they may even go on with the action, in many cases, after these latter have taken on the action, and been cured.

The periosteum, fasciæ, tendons, ligaments, and bones, are the parts which are usually affected in the second stage of the lues venerea. Mr. Hunter remarks, however, that we cannot always know with certainty what parts may become affected in this stage of the disease. He says, he has known the distemper produce a total deafness, sometimes followed by suppuration, and great pain in the ear, and side of the head. We have already explained, that it was one of this gentleman's doctrines, that

the second order of parts were generally deep-seated. When these become irritated by the poison, he observes, that the progress of the disease is more gradual, than in the first order of parts. It assumes very much the character of scrophulous swellings, or chronic rheumatism; only it affects the joints, less frequently, than the latter affection does. A swelling sometimes makes its appearance on a bone, when there has been no possible means of catching the infection for many months; and, in consequence of the little pain experienced, the tumour may be of some considerable size, before it is noticed. Sometimes, a great deal of pain is felt; but, no swelling comes on, till after a long while. Mr. Hunter states, that these remarks are also applicable to swellings of the tendons, and fasciæ. As tumours of this kind only increase by slow degrees, they are not attended with symptoms of much inflammation. When they attack the periosteum, they seem like an enlargement of the bone itself, in consequence of being very firm, and closely connected with the latter part. Mr. Hunter also further observes, that, in these advanced stages of the disease, the inflammation can hardly get beyond the adhesive kind, in which state, it continues to become worse and worse, and when matter is formed, it is not true pus, but of a slimy description. Some nodes, he says, both of the tendons and bones, last for years, before they form any matter at all. These cases, he mentions as not being certainly venereal, though commonly considered as such.

It is not easy to explain the reason, why, when lues venerea attacks the bones, or the periosteum, the pain should sometimes be very considerable, and, sometimes, very trivial. The pains are usually of a periodical kind, being, in general, most severe in the night-time.

At the present day, when venereal cases are cured by much smaller doses of mercury, than were given in Mr. Hunter's time, nodes have become much less frequent, and I have already in a previous part of this article expressed my decided belief, that a disposition to nodes was formerly often occasioned by the abuse of mercury.

TREATMENT OF LUES VENEREA.

The first order of parts, or those which are most susceptible of being affected in lues venerea, are also the most easy of cure; while the second order of parts take more time to be remedied.

In the class of complaints, arising in the second stage of the lues venerea, Mr. Hunter believed, that it was unnecessary to continue the employment of mercury, till all the swelling had disappeared. For, it is observed by this distinguished writer, that, since these local complaints cannot contaminate

the constitution by re-absorption, and since the venereal disposition and action from the constitution can be cured, while the local effects still remain, and this even when the tumefaction, forming nodes on the bones, fasciæ, &c. has proceeded to suppuration, there can be no occasion for continuing the course, after the venereal action has been destroyed. Mr. Hunter thought, that in this latter stage of the lues venerea, the syphilitic irritation was more easy of cure, than the swelling and other effects of that irritation.

Mercury, in the lues venerea, as well as in cases of chancres, is the great specific. In the present state of our knowledge, nothing else can be so well depended upon; but, it should always be employed with moderation, lest it produce worse effects, and more terrible diseases, than those, which it is designed to relieve.

For an account of the various ways of exhibiting this valuable medicine, I must refer the reader to the article *Mercury*, in this Dictionary.

In curing the lues venerea, mercury can only have two modes of action; one on the poison; the other on the constitution. If, says Mr. Hunter, mercury acted on the poison only, one might conceive it did so, either by destroying its qualities, by decomposing it, or else by attracting it and carrying it out of the circulation. If mercury acted in the first of these ways, one would expect, that the cure would depend on the quantity of the medicine taken into the system. If it acted in the second manner, one would infer, that, the progress of the cure would be proportionate to the quantity of evacuation. But, observes Mr. Hunter, if it act upon the principle of destroying the diseased action of the living parts, and of counteracting the venereal irritation, by producing one of a different kind, then, neither quantity alone, nor evacuations, will avail much. He states, that the quickness of the cure depends on quantity, joined with visible effects. However, it is added, that, although the effects, which mercury has upon the venereal disease, are in some degree proportioned to the local effects of the medicine on some of the glands, or particular parts of the body, as the mouth, skin, kidneys, and intestines, yet such effects are not altogether proportioned to these other circumstances. When mercury disagrees with the constitution, so as to produce great irritability and hectic symptoms, this action or irritation, as Mr. Hunter explains, is not a counter-irritation to the venereal disease.

It was also noticed by the same author, that the effects of mercury on lues venerea, are always in proportion to the quantity of the remedy, exhibited in a given time, and the susceptibility of the constitution to the mercurial irritation. He says, that these circumstances require the most minute attention, and that, in order to obtain

the greatest action of mercury with safety, and in the most effectual manner, the medicine must be given, till it produces effects somewhere. However, it must not be exhibited too quickly, in order that a sufficient quantity may be given, before we are obliged to stop, in consequence of the effects. Mr. Hunter justly informs us, that when the local effects are produced too quickly, they prevent a sufficient quantity of the remedy from being taken into the system to counteract the venereal irritation at large.

Mr. Hunter mentions his having seen some cases, in which mercury acted very readily locally, and, yet the constitution was hardly affected by it, for the disease would not give way. He states, that he has met with other cases, in which the mere quantity of mercury did not answer, till it was given so quickly as to affect the constitution in such a manner, as to produce local irritation, and, consequently, sensible evacuations. This, he observes, is a proof, that the local effects of mercury are often the sign of its specific effects on the constitution at large, and it shows, that the susceptibility of the diseased parts to be affected by the medicine, is in proportion to its effects on the mouth. Its effects, he contends, are not to be imputed to evacuation; but, to its irritation. Hence, he inculcates, that mercury should be given, if possible, in such a manner, as to produce sensible effects upon some parts of the body, and in the largest quantity that can be given, to produce these effects within certain bounds. Mr. Hunter also remarks, that these sensible effects should be the means of determining, how far the medicine may be pushed, so as to have the greatest effect on the disease, without endangering the constitution. The practice must vary according to circumstances; and if the disease is in a violent degree, less regard must be had to the constitution, and mercury must be thrown into the system in larger quantities.

Mr. Hunter likewise acquaints us, that, when the disease is in the first order of parts, a smaller quantity of mercury is necessary, than when the second order of parts are affected, and the disease has been of long standing, its first appearances alone being cured, and the venereal disposition still remaining in the secondary parts. For the purpose of curing the venereal disease, whether in the form of chancre, bubo, or lues venerea, Mr. Hunter was of opinion, that probably the same quantity of mercury is necessary. He represents, that one sore requires as much mercury as fifty sores in the same person, and a small sore as much as a large one. He thought, that the only difference, if there is any, must depend upon the nature of the parts affected, that is, on their being naturally active or indolent. He conceived, however, that, on the whole, recent venereal complaints are generally

more difficult of cure, than the symptoms of lues venerea, and that this may make a difference, in regard to the quantity of mercury necessary.

Having now delivered the principal general instructions, relative to the exhibition of mercury in the treatment of the venereal disease, as given by Mr. Hunter, I must not quit the subject, without remarking, that even this eminent surgeon appears on the whole too partial to the long use of mercury, and sometimes to the introduction of immoderate quantities of it into the system. In general, however, his observations tend to condemn all violent salivations. It is to be recollected, that, in his days, nobody had a suspicion that truly syphilitic sores would in the end spontaneously heal, and he himself had no dependance upon any medicine, except mercury, for the cure of the true venereal disease. But, modern experience evinces, that the disorder seldom now presents itself in forms so bad and intractable as formerly; that it is even capable of spontaneously ceasing; and that we hardly ever see cases, in which it is requisite to give mercury, except in very moderate quantities. Indeed, such is the change, that many surgeons suspect that the very nature of the disease must have undergone a material alteration, or modification. In England, in my opinion, every thing is to be referred to the improved manner of employing mercury only in moderate doses, and never pushing its exhibition, till the constitution is so impaired, that undescribable forms of diseases ensue, which are sometimes the compound effect of mercury and syphilis together; and, in other instances, of that description, which surgeons now frequently call *syphiloid*, or *pseudosyphilitic*, not depending upon the venereal poison at all, but upon a state of the system, which mercury is known to aggravate in the worst degree.

The principles above laid down, and other observations, contained in the article *Mercury*, must suffice for the direction of the cure of lues venerea by this great specific remedy. Other information, connected with the subject, will be found by referring to *Acidum Nitricum*, *Guaiacum*, *Mezerion*, *Sarsaparilla*, &c.

With respect to the local treatment of the symptoms of lues venerea, Mr. Hunter thought, that none would in general be necessary, since the constitutional treatment would commonly effect a cure.

The same writer notices, however, that sometimes the local effects will not give way, and the parts remain swollen in an indolent inactive state, even after there is every reason to believe, that the constitution is perfectly cured. In such cases, he recommends assisting the constitutional treatment by local applications of mercury to the part, either in the form of a plaster, or

ointment. The latter application, he says, is the best. When these are not sufficient, he advises an attempt to be made to excite inflammation of another kind. He says, he has seen a venereal node, which gave excruciating pain, cured by merely making an incision down to the bone, the whole length of the node. The pain ceased, the swelling decreased, and the sore healed up kindly, without the assistance of a grain of mercury. He mentions, that blisters have been applied to nodes with success, removing the pain, and taking away the swelling.

With regard to these last cases, I may add, that, for many years past, the idea of completely dispersing nodes by mercury has been entirely abandoned in St. Bartholomew's hospital. In this institution, long protracted mercurial courses for the cure of such swellings are totally relinquished. When small moderate quantities of mercury have had their full effect, a blister is applied over the swelling, and kept open, under which plan the tumour generally subsides as far as its nature will allow.

It is curious, that a venereal ophthalmia, that very case whose real existence was doubted by Hunter, is a thing, that has been lately pointed out as an actual criterion of syphilis, when other symptoms only afford suspicion and doubt. "There is (says Mr. Carlisle) one sign, which I have never found to deceive me, whenever it occurs; and that is an ophthalmia, where the pupil is irregularly contracted, so as to destroy its circular appearance. The venereal inflammation of the iris draws the pupil into corners, or angular lines. At first, it is often accompanied by a muddiness of the transparent front of the eye; but, whether in the aqueous humour, or in the cornea, is not certain. The same inflammation, when very active, generally extends to the choroid membrane, and renders the eye highly irritable to light. Whenever the pupil is thus deformed, and any other, even equivocal signs of syphilis exist, I deem it a sufficient evidence for the employment of mercury. I have often seen the venereal ophthalmia put on the chronic type, and, in one instance, the choroid veins in a distended state, protruded through the pupil. The whole globe of the eye was at the same time much enlarged, and the organ was totally spoiled. After a seven week's course of mercury, the eye recovered its natural size, the veins disappeared, and a partial vision returned. In another example, I saw a distinct venereal ulcer, with a protruding margin, upon the iris, discharging pus into the aqueous chamber, and which was shewn at the time to all the students of the Westminster Hospital. It healed during the second week of the mercurial course, and all the attendant venereal symptoms dispersed at the close of the seventh week." (See *London Med. Repository*, Vol. 7, p. 91.) Mr. Carlisle also consi-

ders gummi as another distinguishing mark of the venereal disease. "Those swellings, (he observes) appear to be formed in the adipose membrane, and their locality is not regulated; they are usually the concomitants of an obscure state of the disease; they seem especially to follow the inefficacious use of mercury, or a mild form of original infection. They are more often a ternary and distant recurrence of the disease, than a secondary and speedy re-appearance. They most frequently arise in apparently ill-conditioned habits, and are slow in their progress. I have many times adopted this leading symptom to decide upon the case, when all the other evidences were unsatisfactory." (Op. cit.) Mr. Carlisle thinks, also, that there is constantly a cadaverous aspect attending all constitutional venereal affections. He asserts, that he has seen a venereal pneumonia; and a syphilitic carbuncle.

DISEASES RESEMBLING THE VENEREAL.—
PSEUDO-SYPHILIS.

Sores on the glans penis, prepuce, &c. in the form of chancres, as Mr. Hunter notices, may and do arise without any venereal infection, although in general they are a consequence of former venereal sores, which have been cured.

The symptoms, produced by the venereal poison in the constitution, are such as are common to many other diseases. For instance, Mr. Hunter remarks, that blotches on the skin are common to what is called a scorbutic habit; pains are common to rheumatism; swellings of the bones, periosteum, fasciæ, &c. to many bad habits, perhaps, of the scrophulous and rheumatic kind. Thus, says this valuable writer, most of the symptoms of the venereal disease, in all its forms, are to be found in many other diseases. Hence, the original cause, and many leading circumstances, such as dates, effects of the disorder upon others, from connexion, when only local, the previous and present symptoms, &c. must be considered, before we can determine absolutely what the disease truly is. All the circumstances and symptoms, taken together, may be such, as will attend no other disease. However, Mr. Hunter confesses, that with all our knowledge, and with all the application of that knowledge to suspicious symptoms of this disease, we are often mistaken, calling distempers venereal, which are not so, and sometimes supposing really syphilitic affections to be of another nature.

Mr. Hunter takes notice, that, in some constitutions, rheumatism, in many of its symptoms, resembles the lues venerea. The nocturnal pains, swelling of the tendons, ligaments, and periosteum, and pain in those swellings, are symptoms both of the rheumatism, and also of the venereal disease,

when it attacks such parts. Mr. Hunter, however, did not know, that he had ever seen the lues venerea attack the joints, though many rheumatic complaints of such parts are cured by mercury, and therefore supposed to be venereal.

Mercury, given without caution, often produces the same symptoms as rheumatism. Mr. Hunter has seen such complaints supposed to be venereal, and the medicine continued.

This interesting author also explains, that some diseases not only resemble the venereal in appearance, but, in the mode of contamination, proving themselves to be poisons by affecting the part of contact; then producing immediate consequences similar to buboes; and also remote consequences similar to the lues venerea.

Mr. Hunter observes, that it is nearly as dangerous, in some constitutions, to give mercury, when the disease is not venereal, as to omit it in other cases, which are really syphilitic. Many of the constitutions, which put on some of the venereal symptoms, when the disease is not really present, are those, with which mercury seldom agrees, and commonly does harm. Mr. Hunter has seen mercury, which was exhibited for a supposed venereal ulcer of the tonsils, produce a mortification of those glands, and the patient was nearly destroyed.

Mr. Abernethy, in his *Surgical Observations*, 1804, has treated at some length of diseases resembling syphilis, and has adduced several very interesting cases, which I advise every surgical practitioner to read with the greatest attention. The following case, recorded by this gentleman, I shall take the liberty of quoting.

"A gentleman (says Mr. Abernethy) thought, that he had infected a slight cut on his hand (which was situated in front of and just below the little finger) with the discharge from a bubo in the groin, that he had occasion to open. The wound fretted out into a sore about the size of a sixpence, which he shewed me, and which I affirmed had not the thickened edge and base, and other characters of a venereal chancre. I therefore recommended him to try the effect of local means, and not to use mercury.

"In about a month the sore, which had spread a little, became again contracted in its dimensions, and assumed an healing appearance. At this time pain was felt extending up the arm, and suddenly a considerable tumour arose over the absorbing vessels, which proceed along the inner edge of the biceps muscle. This tumour became nearly as big as a small orange. As the original sore seemed now disposed to heal, and as there was no surrounding induration, I could not believe it venereal, and therefore recommended him still to abstain from mercury, and apply leeches and linen moistened in the aq. litharg. acet. comp. to the tumour

formed over the inflamed absorbents. For it seemed to me, that if the venereal poison had been imbibed from the sore, it would have passed on to one of the axillary glands, and would have caused induration and inflammation to take place there, more slowly, than had occurred on the present occasion.

"Under this treatment the tumour was discussed, and the sore at the same time healed. About three weeks afterwards the patient called on me, and said that there were venereal ulcers in his throat; and in each tonsil there was an ulcer deeply excavated, with irregular edges, and with a surface covered by adhering matter; ulcers, in short, which every surgeon, who depends on his sight as his guide, would have pronounced to be venereal. Shortly after also, some copper-coloured eruptions appeared on his face and breast. He shewed his diseases to several surgeons, on whose opinion he relied, who, without hesitation, affirmed that they were venereal, and that the mercurial course had been improperly delayed.

"Whilst the patient was looking out for lodgings, in order that he might go through the mercurial process, a circumscribed thickening and elevation of the pericranium covering the frontal bone, appeared: it was of the circumference of an half-crown piece; and was, in short, what every surgeon, who is guided only by his sight and touch, would, without hesitation, have called a fair corona veneris. I now told the patient that I was more inclined to believe his disease was not syphilitic, from the sudden and simultaneous occurrence of this node with the sore throat, &c. Other surgeons thought differently; and I believe this very sensible and amiable young man imagined, that his health would become a sacrifice, if he any longer attended to my opinion. He was preparing to submit to a mercurial course, when very important concerns called him instantly into the country. He went with great reluctance, taking with him mercurial ointment, &c.: and after a fortnight I received a letter from him, saying that he found his complaints benefited by his journey, that business had prevented him from beginning the use of mercury for a few days, that he now found it was unnecessary, for his symptoms had almost disappeared, and shortly afterwards he became perfectly well."

Mr. Abernethy considers this case as the most unequivocal instance extant of a disease occurring, which could not from appearance be distinguished by surgeons of the greatest experience from syphilis, and which, however, was undoubtedly of a different nature. He believes, that

there is no one, who would not have decided on this case, as those did who declared it to be venereal, unless they had had an opportunity of very attentively watching its progress.

Mr. Abernethy, in the course of his remarks, makes it appear, that cases, which are venereal, and others, which are not, cannot in general be discriminated by the mere aspect of the affections. He believes, however, that there are some circumstances, in the progress of such different distempers, from which a line of distinction might be drawn.

A very simple fact has enabled this gentleman in most cases to distinguish the two diseases: "yet, simple as it is, (says Mr. Abernethy,) if it be generally true, it is very important; and if it were universally true, it would be of the highest consequence. The fact alluded to is, that the constitutional symptoms of the venereal disease are generally progressive, and never disappear unless medicine be employed. It may be added too, they are as generally relieved under an adequate effect of mercury on the constitution, &c.

"I have asked the opinion of several surgeons of great practice and abilities respecting this question; Whether constitutional symptoms of syphilis do ever spontaneously amend? and no one has decidedly replied in the affirmative, whilst all, without hesitation, agreed that they were generally progressive till checked by the effect of mercury. It seemed useless to seek further information; for what surgeon is there, at present, if he sees diseases, that cannot be distinguished by the sight from syphilis, and hears that they arose in consequence of a chancre, that would suspend his judgment, and forbear to administer mercury? If I have lived in the habit of so frequently detecting the imposing appearances of the secondary effects of these diseases, it is because I have been upon the watch, and because they have occurred in patients, in whom I have seen the primary sores, the appearance and progress of which have excited my suspicion as to their nature. I have stated the rule as general, but not universal; for I could myself relate cases of diseases, in which, from the great abatement, and even disappearance of symptoms, I have concluded the disease was not syphilitic; yet, from the duration of the disorder, or from the subsequent aggravation of its symptoms, the patient has desired, and I have recommended the use of mercury, and the disease has been treated as venereal, without its real nature being ascertained.

"The rule, which has been mentioned, relates to the constitutional symptoms of the venereal disease; for, the primary ones,

chancres, do sometimes heal spontaneously, generally, however, though not constantly, leaving a thickening or induration of the affected part. They may also be induced to heal by topical means, without mercury, with similar events. Some enlargements of glands in the groin will also in like manner subside.

"It may be fairly supposed, that if some chancres heal spontaneously, that constitutional diseases arising from the same cause, may, in like manner, sometimes get better without medicine. The administration of nitrous acid, opium, and other remedies have been said to have amended, if not entirely cured, these constitutional diseases. But the question is, will they get better spontaneously? and the question can only be solved by experience. Delay will frequently enable a surgeon to decide; but, there are cases, in which no amendment takes place, and the surgeon is as it were forced, from the progress of the disease, to employ mercury.

"In recommending prudent delay and attentive observation, I hope and believe, (continues Mr. Abernethy,) that I am not recommending any thing likely to be of dangerous consequence. The venereal disease is generally soon checked by the use of mercury; and in constitutions, where much medicine is required to counteract its effects, that medicine may be given with freedom. By delay and observation, we perhaps may perceive, that eruptions and sore throats, which could not from appearance be distinguished from venereal, spontaneously amend: that some eruptions scale and become well, and the probability will of course be that the rest will do so likewise: or that an ulcer mends in one part though it may spread in another, when the natural inference is that the diseased actions in the sore will gradually cease, and health return spontaneously; and that what has occurred in one part of an ulcer, will successively take place in another.

"In recommending delay it cannot, I suppose, be thought that I would advise any one to wait till an ulcer destroyed the velum pendulum palati, or did material injury to any important part. There are cases where the progress of the disease obliges a surgeon to use mercury, even though he may be suspicious that it is not syphilitic. The effect of exciting a mercurial affection of the constitution in diseases resembling syphilis is, as far as my observation enables me to determine, very various. It sometimes cures them very suddenly and very differently from the gradual amendment, which it produces in truly venereal diseases. Sometimes, however, these diseases yield more slowly to its operation, and are cured

permanently. Sometimes the diseases recur in the same parts after a severe course of mercury; sometimes mercury merely checks the disease, and can scarcely be said to cure it; in which case it seems important to support the strength of the constitution, and to keep up that mercurial effect which controuls the disease, and can be borne without material derangement of the constitution for a great length of time. Sometimes also the use of mercury aggravates these diseases.

"Again, in some constitutions, the venereal disease may assume unusual characters, and be very difficult to cure. It must then be scarcely possible to discriminate between these anomalous cases of syphilis and those of diseases resembling it, unless some new distinctions are discovered." (See *Surgical Observations*, by John Abernethy, F. R. S.)

Some years ago the nitric acid was introduced as a remedy in syphilis. (See *Acidum Nitrosum*.) It was first thus employed in India, where it appeared to cure the disease; but, of late years, its use has been nearly discontinued in England in all unequivocal venereal cases, on the ground of its being less efficacious, than mercury, and less to be depended upon. Dr. Scott, who first suggested its use, has lately attempted to account for this failure, by observing that the acid he employed was not pure nitric acid, but an impure acid, containing an admixture of muriatic acid. He therefore some time ago recommended the use of a compound acid, containing three parts of nitric acid, and one of muriatic; which he administered internally, and also applied externally, largely diluted, as a bath, until the gums were affected and ptyalism produced; and he conceived every trial as quite inconclusive, unless these constitutional effects occurred. Of late, however, he has employed the acids in equal weights.

"The acid, that I have used of late (says Dr. Scott,) is the nitro-muriatic; and it is formed by mixing together equal parts of the nitrous, or nitric acid, and muriatic acid. If these acids be in the state of concentration, that they usually possess in the shops, and if the quantities be considerable, a great volume of gas is evolved on their coming into contact, which taints every part of a house, is extremely hurtful to the lungs, and disagreeable to the smell. To avoid this inconvenience, I put a quantity of water, at least equal in bulk to both the acids, into a bottle, and I add the acids to it separately. This method does not only prevent the unpleasant odour, but it tends to retain the chlorine, on which its effects depend. It is well known, that the nitro-muriatic acid acts very readily on the metals and earth;

nothing therefore, but glass, or extremely well glazed vessels of porcelain, should be used to contain it. Wooden tubs for bathing answer very well, and they should always be made *as small as possible*, compatible with their holding the body, or the limbs that we wish to expose to the bath. From their being small, we save acid, and are able to heat the bath with ease. In India, I have often exposed the whole body below the head to this bath; but here I have been satisfied in general with keeping the legs and feet exposed to it. In order to warm the bath, after the first time, I have commonly made a third, or a fourth, part of it be thrown away, and the loss replaced by boiling water and a proportional quantity of acid. To save the expenditure of acid, I have occasionally warmed a portion of the bath in porcelain vessels, placed near the fire, but I fear this may diminish its effects.

"It is no easy matter (continues Dr. Scott) to give directions, with regard to the degree of acidity of the bath. I have commonly made it about as strong as very weak vinegar, trusting to the taste alone. The strength should be regulated by the degree of irritability of the patient's skin. I may say, that although I like to know, that it is strong enough to prick the skin a very little, after being exposed to it from fifteen to thirty minutes, yet I believe that even such an effect as this is unnecessary.

"The time too of remaining in the bath, in order to produce the greatest effect, is a matter of doubt. I have kept the legs and feet exposed to it for half an hour, or more; but, with more delicate people, not above one half, or one third of that time. I have repeated these baths daily, or even twice, or thrice a day." (See *Medical and Chirurgical Trans.* Vol. 8, p. 181.) Dr. Scott adds, that the mere sponging the skin with nitro-muriatic acid, sufficiently diluted with water, gives rise to the very same effects as bathing, and is more easily adopted. Fifteen, or twenty minutes may be employed in the sponging, though he has found, that a much less time does produce very material effects."

Dr. Scott has found the nitro-muriatic acid particularly useful, even in this country, in that description of syphilis, which is termed pseudo-syphilis, and which he considers as real syphilis combined with scrophula, called into action by the mercury employed for the cure of the syphilitic affection, and consequently not curable by mercury, although syphilis be still in the habit, but undoubtedly not produced by that remedy. He attributes the beneficial effects to the chlorine, which is loosely combined in this compound. (See *Journal of Science and the Arts*, Vol. 1, p. 205—211; Lon-

don Medical Repository, Vol. 7, p. 59; and *Medical and Chir. Trans.* Vol. 8, p. 173, et seq.)

Of the nitro-muriatic acid I have had no experience myself; but, I have always been accustomed to prescribe the nitric acid for diseases resembling syphilis, with decidedly beneficial effect. At Paris, during the winter before last, I used this medicine in several pseudo-syphilitic cases, and I thought more good was derived from it than any thing else, which was tried. The case of a surgeon, who was there under my care, would be interesting; but, my limits will not allow me to insert it.

For information concerning the venereal disease, the reader should particularly consult *Astruc de Morbis Venereis*. *John Vigo's Whole Works in Chirurgie*, by Gale, 1586; or the Latin edition published at Leyden, in 1518. *Fallopian de Morbo Gallico*. *Antonius Musa Brasavolus in the Aphrodisiacus*. *Ulricus de Hutten de Morbo Gallico*. *Boerhaavius de Lue Venerea*, 12mo. 1751. *Rondeletti Opera Omnia*, 4to; Geneva, 1610. *Morgagni de Sedibus et Causis Morborum*. *Franciscus de Morbo Gallico*, 8vo. VERRUCA. A wart. (See *Wart*.)

VERTEBRÆ, DISEASE OF.

The disorder, which we are going to consider, is a disease of the spine, attended with a more, or less, complete loss of the power of using the legs.

From Mr. Pott we learn, that formerly it was generally called a palsy, and treated as a paralytic affection; to which it is in almost every respect perfectly unlike.

In the true paralysis, (says Mr. Pott,) from whatever cause, the muscles of the affected limb are soft, flabby, unresisting, and incapable of being put into even a tonic state; the limb itself may be placed in almost any position, or posture; if it be lifted up, and then let go, it falls down, and it is not in the power of the patient to prevent, or even to retard its fall: the joints are perfectly and easily moveable in any direction; if the affection be of the lower limbs, neither hips, knees, nor ankles, have any degree of rigidity, or stiffness; but, permit the limb to be turned, or twisted, in almost any manner.

In the present case, the muscles are indeed lessened, but, they are rigid, and always at least in a tonic state, by which the knees and ankles acquire a stiffness not very easy to overcome. By means of this stiffness, mixed with a kind of spasm, the legs of the patient are either constantly kept stretched out straight, in which case considerable force is required to bend the knees, or they are, by the action of the stronger muscles, drawn across each other, in such manner as to require as much to separate them. When the leg is in a straight position, the extensor muscles act so powerfully, as to require a considerable degree of force, to bend the joints of the knees; and, when they have been bent, the legs are immediately, and strongly, drawn up, with the heels toward the buttocks. By the rigidity of the ankle-joints joined to the spasmodic action of the gastrocnemii muscles, the patient's toes are pointed downward, in such manner as to render it impossible for him to put his foot flat to the ground: which makes one of the decisive characteristics of the distemper.

These (says Pott) are strong marks of the distinction, which ought to be made between the two diseases; and, fully sufficient to shew the impropriety of confounding them with each other.

The majority of those, who labour under this disease, are infants, or young children: adults are by no means exempt from it; but Mr. Pott never saw it at an age beyond forty.

Mr. Pott remarks, that, when it attacks a child, who is old enough to have walked properly, its awkward and imperfect manner of using its legs, is the circumstance, which first excites attention, and the incapacity of using them at all, which very soon follows, fixes that attention, and alarms the friends.

The account, most frequently given, is, that for some time previous to the incapacity, the child had been observed to be languid, listless, and very soon tired; that he was unwilling to move much, or briskly; that he had been observed frequently to trip and stumble, although no impediment lay in his way; that when he moved hastily, or unguardedly, his legs would cross each other involuntarily, by which he was often and suddenly thrown down; that if he endeavoured to stand still, and upright, unsupported by another person, his knees would totter and bend under him; that he could not, with any degree of precision or certainty, steadily direct either of his feet, to any particular point, but, that in attempting so to do, they would be suddenly, and involuntarily brought across each other; that soon after this, he complained of frequent pains and twitchings in his thighs, particularly when in bed, and of an uneasy sensation at the pit of his stomach; that when he sat on a chair, or a stool, his legs were almost always found across each other, and drawn up under the seat; and that in a little time after these particulars had been observed, he totally lost the power of walking.

The same author observes, that if the incurvation be of the neck, and to a considerable degree, by affecting several vertebræ, the child finds it inconvenient and painful to support its own head, and is always desirous of laying it on a table or pillow, or any thing to take off the weight. If the affection be of the dorsal vertebræ, the general marks of a distempered habit, such as loss of appetite, hard dry cough, laborious respiration, quick pulse, and disposition to hectic, appear pretty early, and in such a manner as to demand attention: and as, in this state of the case, there is always, from the connexion between the ribs, sternum, and spine, a great degree of crookedness of the trunk, these complaints are by every body set to the account of the deformity merely.

Mr. Pott states, that an adult, in a case, where no violence has been committed, or received, will tell you, that his first intimation was a sense of weakness in his back-bone, accompanied with what he will call a heavy dull kind of pain, attended with such a lassitude, as rendered a small degree of exercise fatiguing: that this was soon followed by an unusual sense of coldness in his thighs, not accountable for from

the weather, and a palpable diminution of their sensibility. That in a little time more, his limbs were frequently convulsed by involuntary twitchings, particularly troublesome in the night; that soon after this, he not only became incapable of walking, but that his power either of retaining or discharging his urine and feces, was considerably impaired, and his penis became incapable of erection.

The adult also finds all the offices of his digestive, and respiratory organs much affected, and complains constantly of pain and tightness at his stomach.

In infants, the curve is seldom noticed till it has got to such size and state, as to demand attention from the deformity: previous to this, all the marks of distemper, which appear in the child, pass for the effects of general weakness, and are treated as such.

In an adult, the disease passes for rheumatism, or gravel, or a strain, and the defect in the limbs is the first thing, that occasions an enquiry into the state of the back-bone.

When a curvature, says Mr. Pott, is perceived in an infant, it is always supposed to have received a hurt by a blow, or fall, and an adult has always recourse to some exertion in pulling, drawing, lifting, or carrying, by which the spine is thought to have been deranged, or injured; but which supposition is seldom, if ever true, in either case.

The true cause of the disease, is a morbid state of the spine, and of some of the parts connected with it; which distempered state of parts will, upon careful enquiry, be always found to have preceded the deformity some length of time; in infants, this is the sole cause, and external violence has nothing to do with it. In the adult, (continues Mr. Pott,) I will not assert, that external mischief is always and totally out of the question; but, I will venture to affirm, what is equal, as far as regards the true nature of the case, which is, that although accident and violence may in some few instances be allowed to have contributed to its more immediate appearance, yet the part, in which it shews itself, must have been previously in a morbid state, and thereby predisposed for the production of it. I do not (says Mr. Pott) by this mean to say, that a violent exertion cannot injure the spine, nor produce a paralytic complaint, that would be to say more than I know; but, I will venture to assert, that no degree of violence whatever is capable of producing such an appearance as I am now speaking of, unless the bodies of the vertebræ were by previous distemper disposed to give way; and that no supposable dislocation, caused by mere violence done to the bones of the back,

which bones were, before the receipt of the injury, in a sound state, can possibly be attended with the peculiar symptoms of a curved spine.

According to Mr. Pott, the true curvature is invariably uniform, in being from within outwards; but, it varies in situation, in extent, and in degree; it affects the neck, the back, or the loins; it comprehends one vertebra only, or two, or more; and as few or more are affected, or, as these are more or less morbid, and, consequently give way more or less, the curve must be different; but, whatever variety these circumstances may admit, the lower limbs alone usually feel the effect. Mr. Pott, however, had seen two cases, in one of which the arms only were affected; in the other, both legs and arms. Mr. Ford shewed him a lad, who had lost the use of both arms and legs from a curvature. An account of two similar examples was also communicated to Mr. Pott by Mr. Parke, of Liverpool. Some are, very soon after the curvature, rendered totally and absolutely incapable, not only of walking, but of using their legs in any manner; others can make shift to move about with the help of crutches, or by grasping their thighs just above the knees with both hands; some can sit in an armed chair, without much trouble or fatigue; others cannot sit up with any help; some retain such a degree of power of using their legs, as to be able to shift their posture when in bed; others have no such power, and are obliged to be moved upon all occasions.

Mr. Pott adds, that weak and delicate children are the most frequent subjects of this distemper; and when in these, it seizes on the dorsal vertebræ, great deformity of the trunk, both before, and behind, is the almost inevitable and necessary consequence; this will be different in different persons; but, let the difference in this be what it may, it is an adjunct circumstance, and upon due enquiry it will always be found, that the curvature from within outward, preceded the other deformity, and was, at one time, the only one to be seen.

Before the alteration of figure in the back-bone has been discovered, says Mr. Pott, all the attention is paid to the limbs, in which the whole disorder is supposed to reside; and all the applications for relief are made to them: frictions, liniments, embrocations, blisters, &c. to which is generally added cold bathing and electricity; when the curvature has been noticed, recourse is immediately had to back-boards, collars, steel boddices, swings, screw-chairs, and other pieces of machinery, but all to no purpose; the patient becomes daily more and more helpless and unhealthy, languishes for more or

less time, and at last dies, either in an emaciated state, from an hectic, or by a drain from an abscess, formed within the body.

Mr. Pott contends, that the primary and sole cause of all the mischief, is a distempered state of the parts composing, or in immediate connexion with the spine, tending to, and most frequently ending in, a caries of the body, or bodies, of one or more of the vertebræ: from this proceed all the ills, whether general, or local, apparent or concealed; this causes the ill health of the patient, and, in time, the curvature. The helpless state of the limbs, is only one consequence of several, proceeding from the same cause; but, though this effect is a very frequent one, and always affects the limbs in nearly the same manner; yet, the disease not having its origin in them, no application made to them only, can ever be of any possible use.

The same failure of success (observes Mr. Pott) attends the use of the different pieces of machinery, and, for reasons, which are equally obvious.

They are all (says this author,) from the most simple, to the most complex, but particularly the swing and the screw, calculated to obviate and remove what does not exist. They are founded upon the supposition of an actual *dislocation*, which never is the case, and therefore they always have been, and ever must be, unsuccessful.

Mr. Pott states, that the bones are either already carious, or tending to become so; the parts connected with them are diseased, and not unfrequently ulcerated; there is no displacement of the vertebræ, with regard to each other, and the spine bends forward only because the rotten bone, or bones, intervening between the sound ones, give way, being unable, in such state, to bear the weight of the parts above. The most superficial reflection on this, must point out to every one, why attempts of this kind can do no good, and a little more attention to the subject will shew, why they may be productive of real, and great mischief.

Mr. Pott observes: When a child appears to be what the common people call naturally weakly, whatever complaints it may have, are supposed to be caused by its weak state, and it is generally believed, that time and common care will remove them; but, when a curvature has made its appearance, all these marks of ill health, such as laborious respiration, hard cough, quick pulse, hectic heat and flushing, pain and tightness of the stomach, &c. are more attentively regarded, and set to the account of the deformity consequent to the curve, more especially if the curvature be of the dorsal vertebræ, in which case the defor-

mity is always greatest: but, whoever will carefully attend to all the circumstances of this disorder, will be convinced, that most, if not all the complaints of children, labouring under this infirmity, precede the curvature, and that a morbid state of the spine, and of the parts connected with it, is the original and primary cause of both.

Amongst many other reasons for thinking, that an effect was mistaken for a cause, Mr. Pott enumerates the following.

1. "That he did not remember ever to have seen this useless state of the limbs from a mere mal-formation of the spine, however crooked such mal-formation might have made it.

2. "That none of those deviations from right shape, which growing girls are so liable to, however great the deformity might be, was ever attended with this effect.

3. "That the kind of deformity, which was attended with this affection of the limbs, although it was different as to its degree, and its extent, in different people; yet, it was uniform in one circumstance, which was, that the curvature always was from within outwards.

4. "That since he had been particularly attentive to the disorder, he had observed, that neither the extent, nor degree of the curve, had in general produced any material difference in the symptoms, but that the smallest was, when perfectly formed, attended with the same consequences as the largest."

The first suggestion of the probability, that issues might prove serviceable in this disease, appears to have been made to Mr. Pott in a conversation which passed between him and the late Dr. Cameron, of Worcester, who told him that having remarked in Hippocrates, an account of a paralysis of the lower limbs, cured by an abscess in the back, he had, in a case of useless limbs, attended with a curvature of the spine, endeavoured to imitate this act of nature, by exciting a purulent discharge, and that it had proved very beneficial; which was confirmed to Mr. Pott by Mr. Jeffreys of Worcester, who had made the same experiment with the same success.

If the cure of this most dreadful distemper, observes Mr. Pott, had depended upon an application to the constitution in general, it might have required a variety of medicines, the administration of which must have demanded judgment, in adapting them to particular persons and constitutions; and it must also, in the nature of things, have happened, that many individuals could not have been benefited at all. But, fortunately for the afflicted, the means of relief are simple, uniform, and safely applicable to every individual, under almost every possible circumstance, not attended

by the smallest degree of hazard, and capable of being executed by any body, who has the least portion of chirurgic knowledge; it consists merely in procuring a large discharge of matter, from the integuments, on each side of the distempered bones forming the curvature, and in maintaining such discharge until the patient shall have recovered his health and limbs. They who are little conversant with matters of this sort, (continues Mr. Pott,) will suppose the means very inadequate to the proposed end; but they who have been experimentally acquainted with the very wonderful effects of purulent drains, made from the immediate neighbourhood of diseases, will not be so much surprised at this particular one; and will immediately see how such kind of discharge, made, and continued from the distempered part, checks the further progress of the caries, gives nature an opportunity of exerting her own powers of throwing off the diseased parts, and of producing, by incarnation, an union of the bones (now rendered sound), and thereby establishing a cure.

Mr. Pott states, that it is a matter of very little importance towards the cure, by what means the discharge be procured, provided it be large, that it come from a sufficient depth, and, that it be continued for a sufficient length of time.

I have tried, says he, the different means of setons, issues by incision, and issues by caustic, and have found the last in general preferable, being least painful, most cleanly, most easily manageable, and capable of being longest continued.

The caustics, he observes, should be applied on each side of the curvature, in such a manner as to leave the portion of skin covering the spinal processes of the protruding bones, entire and unhurt, and so large, that the sores, upon the separation of the eschars, may easily hold each three or four peas, in the case of the smallest curvature; but, in large curves, at least as many more.

The issues, which modern surgeons usually make, for the relief of the symptoms arising from diseased vertebræ, are larger, than such as Mr. Pott himself was in the habit of forming. Practitioners now commonly prefer making an issue on each side of the spinous processes, about three, or four inches long, and half an inch broad. This leads me to speak of the method of making caustic issues in general, and of the best way of keeping them open.

The size of the issue, intended to be made, being determined, the place, where it is to be made, should be accurately marked out with ink. All the skin immediately around should then be covered with adhesive plaster, in order that it may be protected from the action of the caustic.

Let the surgeon next take a piece of potassa, or of potassa cum calce, and wrap a little tow round one end of it, so that he may take hold of it with safety and convenience. The other end of the caustic should then be moistened a little, and rubbed very quickly on the portion of the integuments which is to be converted into an eschar. The caustic is to be rubbed in this manner, till the part turns of a dull brown colour, when the caustic should be carefully washed off with a little wet tow, and a poultice applied.

As soon as the eschars admit of being removed, a row of peas, or beans, connected together with thread, should be laid on the sore, and confined there with sticking plaster. A compress, containing a piece of pasteboard, or sheet lead, is then to be bound over the peas, or beans, with a roller. In consequence of the continued pressure, the peas, or beans, soon form little hollows for themselves, in which they should be regularly placed every day. When the pressure is not duly maintained, the granulations are apt to rise so high, that the peas cannot be well kept on the part. In this circumstance, the surgeon must try to repress the high surface of the sore, by sprinkling on it a little of the pulvis sabinae et æruginis æris, mixed together in equal proportions. When this plan is unavailing, the re-application of the caustic becomes indispensable.

With respect to the treatment of diseased vertebræ, Mr. Pott observes, whatever length of time it may take to obtain a complete cure, by restoring the health as well as the limbs, the issues must be continued at least as long; and in his opinion, a considerable time longer, especially in the persons of infants and growing children.

Mr. Pott maintains, that this, and this only, does, or can, alleviate the misery attending this distemper, and in proper time effect a cure.

By means of these discharges, says he, the caries is first checked, and then stopped; in consequence of which an incarnation takes place, and the cartilages between the bodies of the vertebræ having been previously destroyed, the bones become united with each other, and form a kind of ankylosis.

According to Mr. Pott, nothing can be more uncertain than the time required for the cure of this distemper. He has seen it perfected in two or three months; and he has known it require two years; two thirds of which time passed before there was any visible amendment.

This author represents, that after the discharge has been made some time, very uncertain what, the patient is found to be better, in all general respects, and if of age to distinguish, will acknowledge, that

he feels himself to be better in health; he begins to recover his appetite, gets refreshing sleep, and has a more quiet, and less hectic kind of pulse; but, the relief, which he feels above all others, is from having got rid of that distressing sensation of tightness about the stomach; in a little time more a degree of warmth, and a sensibility is felt in the thighs, which they had been strangers to for some time; and generally much about the same time, the power of retaining and discharging the urine and feces begins to be in some degree exerted.

The first return of the power of motion in the limbs, says Mr. Pott, is rather disagreeable; the motions being involuntary, and of the spasmodic kind, principally in the night; and generally attended with a sense of pain in all the muscles concerned.

At this point of amendment, if it may be so called, it is no uncommon thing, especially in bad cases, for the patient to stand some time without making any farther progress; this, in adults, occasions impatience, and in parents, despair; but, in the milder kind of case, the power of voluntary motion generally soon follows the involuntary.

The knees and ankles, by degrees, lose their stiffness, and the relaxation of the latter enables the patient to set his feet flat upon the ground, the certain mark that the power of walking will soon follow; but those joints, having lost their rigidity, become exceedingly weak, and are not for some time capable of serving the purpose of progression.

The first voluntary motions are weak, not constantly performable, nor even every day, and liable to great variation, from a number of accidental circumstances, both external and internal.

The first attempts to walk (continues Mr. Pott) are feeble, irregular, and unsteady, and bear every mark of nervous and muscular debility; the patient stands in need of much help, and his steps, with the best support, will be irregular and unsteady; but, when they have arrived thus far, this eminent surgeon had never seen an instance, in which they did not soon attain the full power of walking.

Mr. Pott adds, that when the patient can just walk, either with crutches, or between two supporters, he generally finds much trouble and inconvenience, in not being able to resist, or to regulate the more powerful action of the stronger muscles of the thigh over the weaker, by which his legs are frequently brought involuntarily across each other, and he is suddenly thrown down.

Adults find assistance in crutches, by laying hold of chairs, tables, &c. but the best and safest assistance for a child, is what is called a go-cart, of such height as

to reach under the arms, and so made as to inclose the whole body: this takes all inconvenient weight off the legs, and at the same time enables the child to move them as much as it may please.

An attentive examination of the morbid appearances, and their effects, in different subjects, led Mr. Pott to conclude, amongst other things, that the disease, which produces these effects on the spine, and the parts in its vicinity, is what is in general called scrophula; that is, that same kind of indisposition as occasions the thick upper lip, the tedious obstinate ophthalmia, the indurated glands under the chin, and in the neck, the obstructed mesentery, the hard dry cough, the glairy swellings of the wrist and ankles, the thickened ligaments of the joints, the enlargement and caries of the bones, &c. &c. &c.

That ulceration or caries of the bodies of the vertebræ affected is the common morbid change and not enlargement.

That the curvature, which in this particular affection is always from within outward, is caused by the erosion, or destruction, of part of the body or bodies of one or more of the vertebræ; by which means that immediately above the distemper, and that immediately below it, are brought nearer to each other than they should be, the body of the patient bends forward, the spine is curved from within outward, and the tuberosity appears behind, occasioned by the protrusion of the spinal processes of the distempered vertebræ.

That according to the degree of carious erosion, and according to the number of vertebræ affected, the curve must be less or greater.

That when the attack is made upon the dorsal vertebræ, the sternum and ribs, for want of proper support, necessarily give way, and other deformity, additional to the curve, is thereby produced.

That this kind of caries is always confined to the bodies of the vertebræ, seldom or never affecting the articular processes.*

That without this erosive destruction of the bodies of the vertebræ, there can be no curvature of the kind here treated of; or, in other words, that erosion is the *sine quâ non* of this disease; that although there can be no true curve without caries, yet there is, and that not infrequently, caries without curve.

That the caries with curvature and useless limbs, is most frequently of the cervical or dorsal vertebræ, the caries without

* Mr. Pott mentions his having seen two cases in which the bodies of the vertebræ were totally separated from all connexion with the other parts, leaving the membrane, which included the spinal marrow, perfectly bare.

curve, of the lumbar, though this is by no means constant or necessary.

That, in the case of carious spine, without curvature, it most frequently happens, that internal abscesses, and collections of matter are formed, which matter makes its way outward, and appears in the hip, groin, or thigh; or, being detained within the body, destroys the patient: the real and immediate cause of whose death is seldom known, or even rightly guessed at, unless the dead body be examined.

That what are commonly called lumbar and psoas abscesses, are not infrequently produced in this manner, and, therefore, when we use these terms, we should be understood to mean only a description of the course which such matter has pursued in its way outward, or the place where it makes its appearance externally, the terms really meaning nothing more, nor conveying any precise idea of the nature, seat, or origin of a distemper subject to great variety, and from which variety its very different symptoms and events, in different subjects, can alone be accounted for.

That contrary to the general opinion, a caries of the spine is more frequently a cause, than an effect of these abscesses.

That the true curvature of the spine, from within outward, of which the paralytic, or useless state of the lower limbs, is a too frequent consequence, is itself but *one* effect of a distempered spine; such case being always attended with a number of complaints, which arise from the same cause: the generally received opinion, therefore, that all the attending symptoms are derived from the curvature, considered abstractedly, is by no means founded in truth, and may be productive of very erroneous conduct.

That in the case of true curvature, attended with useless limbs, there never is a *dislocation*, properly so called; but that the alteration in the figure of the back-bone, is caused solely by the erosion and destruction of a part of one or more of the corpora vertebrarum; and, that as there can be no true curvature without caries, it must be demonstrably clear, that there must have been a distempered state of parts previous to such erosion; from all which it follows, that this distemper, call it by what name you please, ought to be regarded as the original cause of the whole, that is, of the caries, of the curvature, and all the attendant mischiefs, be they what they may, general or particular.

That when two or more vertebræ are affected, forming a large curve, however perfect the success of the treatment may be with regard to the restoration of health, and limbs, yet the curvature will and must

remain, in consequence of the union of the bones with each other.

That the useless state of the limbs is by no means a consequence of the altered figure of the spine, or of the disposition of the bones with regard to each other, but merely of the caries: of this truth there needs no other proof, than what may be drawn from the cure of a large and extensive curvature, in which three or more vertebræ were concerned: in this the deformity always remains unaltered and unalterable, notwithstanding the patient recovers both health and limbs.

Upon the whole, after due consideration of what has been said concerning the nature of the complaint, its producing cause, and the method by which it is capable of being cured, Mr. Pott says, he would ask, whether the diseased state of the spine, and of the parts connected with it, (which, if not prevented, must produce some of its very dreadful effects,) may not, by a timely use of proper means, be prevented?

He contends, that a morbid state of the parts, previous to deformity, caries, or curve, must be allowed: every complaint of the living, and every appearance in the dead, he says, prove it beyond contradiction or doubt. All the general complaints of persons, afflicted with this disorder, will always, upon careful inquiry, be found to have preceded any degree of deformity, to have increased as the curve became apparent, and to have decreased as the means used for relief took place; the pain and tightness about the stomach, the indigestion, the want of appetite, the disturbed sleep, &c. &c. gradually disappear, and the marks of returning health become observable, before the limbs recover the smallest degree of their power of moving.

Mr. Pott remarks, that on the other hand, it is as true, that when from extent, or degree, or inveteracy of the caries, the issues are found to be unequal to the wished-for effect, the general complaints receive no amendment; but increase until the patient sinks under them.

If all this be true, says Mr. Pott, which that it is, the manifold and repeated experience of many, as well as myself, can amply testify; and if it be found, that the issues are capable of effecting a perfect cure, even after a caries has taken place, and that to a considerable degree, which is also true to demonstration, is it not reasonable to conclude, that the same means, made use of in due time, might prove a preventive? (See *Pott on the Palsy of the lower Limbs.*)

W.

WART. Mr. Hunter observes, that a wart appears to be an excrescence from the cutis, or a tumour forming upon it, by which means, it becomes covered with a cuticle, which is either strong and hard, or thin and soft, just as the cuticle is, which covers the parts, from which the excrescence arises. Warts are radiated from their basis to their circumference. The surface of the radii appears to be pointed, or granulated, like the surface of healthy granulations, with the exception of being harder, and rising higher. The surface, on which a wart is formed, seems only to be capable of producing one; for, the surrounding and connecting surface does not throw out a similar substance. Thus, when a wart has once begun to grow, it rises higher and higher, without becoming larger at its basis. Such excrescences seem to have within themselves the power of growing larger; for, as Hunter remarks, after they have risen above the surface of the skin, on which their basis cannot grow larger, they swell out into a round thick substance, which becomes rougher and rougher.

In consequence of having this structure, warts are very liable to be hurt by bodies rubbing against them, and, from such a cause, they often bleed very profusely, and are rendered sore and painful. (*Treatise on the Venereal Disease*, p. 250, Edit. 2.)

As warts are adventitious substances, and not any part of the original structure of the body, their powers of life are weak. Hence, when stimulated by particular applications, these excrescences generally become smaller and smaller, and, at length, altogether disappear, or drop off.

On this principle, warts may frequently be cured by stimulating them with a powder, composed of *æruugo æris* and *savine* leaves, in equal proportions.

However, the employment of escharotics; the removal of such excrescences with a knife or pair of scissors; or tying their necks with a ligature; is a mode frequently preferred, because the cure is sooner accomplished.

The two last methods are certainly particularly eligible, when the wart has a narrow neck; but, after the removal of the excrescence, it is still proper to touch the root with caustic; for, unless the whole be completely destroyed, the wart will inevitably grow again.

With respect to caustics, the practitioner may use the *potassa cum calce vivâ*, the *argentum nitratum*, or the sulphate of copper. I think a strong solution of the *argentum nitratum* is as efficacious an application of the caustic kind, as any, which can be used in these cases.

Warts on the pudenda, and about the anus, which are often erroneously supposed to be venereal, scarcely ever withstand the effect of the powder of *savine*, and *æruugo æris*.

WHITLOW. (*Panaris*, *Onychia*, *Panaritium*, *Paronychia*.) A whitlow is an inflammation, which occurs about the end of the finger, and is exceedingly painful, and very much disposed to suppurate. The affection is commonly seen attacking the fingers, but the toes are also sometimes the seat of the disease.

Writers usually divide whitlows into four kinds, or degrees.

The first one is the mildest. In this case, a vesicle, filled with matter, commonly arises near the root, or side of the nail, after a preceding superficial inflammation of trivial extent. The matter is situated immediately under the cuticle. Sometimes the abscess takes place under the nail, in which case, the pain is very severe, and not unfrequently shoots upward as far as the external condyle.

The second kind of whitlow is chiefly situated in the cellular substance under the cutis, and, for the most part, occurs at the very end of the finger. In this sort of case, the inflammatory symptoms, especially the pain, are far more violent, than they usually are in inflammations of such little extent. However, although the pain is thus severe, it does not in general extend far from the part affected, unless the tendon partake of the inflammation. Writers usually impute the violence of the pain, and the considerable degree of inflammation attending the complaint, to the hard and unyielding nature of the skin on the finger. To the same cause they also ascribe the difficulty of perceiving any fluctuation, after matter has been formed; and the slowness, with which the pus makes its way outward.

The third kind of whitlow is distinguishable from the others by the following circumstances. With the most excruciating pain, there is very little swelling in the affected finger, but, a vast deal in the hand, particularly, about the wrist, and over the whole fore-arm. The pain ex-

tends to the hand, wrist, elbow, and even the shoulder. When suppuration has taken place, a fluctuation can never be felt in the affected finger, though the undulation of matter may very often be distinctly perceived in the hand, at the wrist, or even somewhere in the forearm. The case is frequently accompanied with a considerable degree of fever. In this species of whitlow, the disease is seated in the tendons and their sheaths, and the power of moving the fingers, and even the whole hand, is lost.

Authors describe the fourth kind of whitlow, as arising principally from an inflammation of the periosteum. The case is attended with one peculiarity, which is, that, however violent the pain may be, it never extends to the hand, and forearm, nor is there any external swelling of the affected finger. Suppuration generally very soon follows, the usual consequence of which is a caries of the subjacent finger-bones.

Whitlows commonly begin on the inside of the fingers; but, they do occasionally commence on the back of these parts, and even on that of the hand. Though pain about the wrist is usually the effect of the inflammation in the finger, yet Acrel makes mention of a case, in which the disorder was altogether confined to the hand itself. (*Vorfälle*, 2 B. p. 191.)

Besides the above species of whitlows, Richter takes notice of a very painful affection of the finger, that has been termed the *dry whitlow*. Acrel relates, that a man, without any particular preceding cause was seized with a very violent darting pain, near the nail of the little finger. The pain sometimes ceased for a few minutes, or hours, and then recurred and lasted for weeks, and months.

At length, it became still more intolerable and unremitting, and extended all up the arm. Hence, the removal of the first painful portion of the finger was determined on. Nothing unnatural was found in the appearance of the integuments and tendons; but, the texture of the bone was quite destroyed, and changed into a fatty substance. (*Acrel, Vorfälle*, 2 B. p. 210.)

Mr. Wardrop has favoured the public with an account of a particular species of whitlow, which from its malignant character, he has denominated the *onychia maligna*. "The commencement of this disease is marked by a degree of swelling, of a deep red colour, in the soft parts at the root of the nail. An oozing of a thin ichor afterwards takes place at the cleft formed between the root of the nail and soft parts, and at last the soft parts begin to ulcerate. The ulcer appears on the circular edge of the soft parts at the root of

the nail, it is accompanied with a good deal of swelling, and the skin, particularly that adjacent to the ulcer, has a deep purple colour. The appearance of the ulcer is very unhealthy, the edges being thin and acute, and its surface covered with a dull yellow, or brown coloured lymph, and attended with an ichorous and very fetid discharge. The growth of the nail is interrupted, it loses its natural colour, and at some places appears to have but little connexion with the soft parts. In this state (says Mr. Wardrop) I have seen the disease continue for several years, so that the toe, or finger, became a deformed bulbous mass. The pain is sometimes very acute; but, the disease is more commonly indolent, and accompanied with little uneasiness. This disease affects both the toes and the fingers. I have only observed it on the great toe, and more frequently on the thumb, than any of the fingers. It occurs, too, chiefly in young people; but, I have also seen adults affected with it." (*Wardrop in Med. and Chir. Trans. Vol. 5, p. 135, 136.*)

The causes of whitlows are generally of a local nature. Writers enumerate the following as the most common: a contusion; suddenly warming the finger when it is exceedingly cold; pricks with needles, or other sharp instruments; and the insinuation of irritating matter into scratches on the finger. A surgeon, in operating for a fistula in ano, has been known to cut his finger, and have in consequence of the accident a very severe and dangerous kind of whitlow. Richter also mentions a person, who had a most obstinate whitlow, in consequence of getting a slight wound on the finger, in examining the head of a horse, that had the glanders. Sometimes, the cause of a whitlow depends on a splinter, which still continues lodged in the part. Very often, no particular cause whatever can be assigned for the complaint.

The different kinds of whitlows are not all to be treated in the same manner.

The first case, which occurs about the root of the nail, ought to be opened as soon as possible. When this plan is not adopted, the matter not only makes its way round the nail, but penetrates more deeply, so as to reach the root of the nail, and occasion a loss of the part. When an effectual opening is not made, the matter is apt to collect again. In general, a detachment of the cuticle takes place, as far as the abscess extends. When the inflammation has been very violent, and the matter has made its way as far as the root of the nail, the nail itself is in general gradually detached, while the denuded portion of the root of the nail acts on the sore as a foreign body, and hinders it from healing. Hence, the

surgeon should repeatedly cut away as much of the lower edge of the nail as he can, and insinuate a little soft lint between the margin of the nail and the sore, in order to keep the latter from being irritated by the former. In proportion as the old nail gradually separates, a new one makes its appearance.

When matter lies under the nail, an opening should be made through the part, as speedily as possible, for the discharge of the abscess. In order to perform this operation, Richter advises the surgeon to scrape, with a piece of glass, the part of the nail to be opened, till it is as thin as it can well be, and then to cut through it with the point of a bistoury.

In the second species of whitlow, suppuration may sometimes be prevented, and the inflammation be resolved, by the timely employment of proper means. When the pain is exceedingly violent, and there is acute fever, it may be advisable to bleed the patient in the arm. In a few severe cases, the application of three or four leeches to the affected finger has been known to procure prompt relief. (*Schmucker.*) Theden thinks, that applying a roller round the finger, hand, and arm, and frequently wetting the two first parts with a lotion, the most certain means of resolving the inflammation. Platner advises the finger to be for some time immersed in water, as warm as the patient can bear. Some recommend the external use of camphorated spirit, or the volatile alkali; while others advise the affected finger to be plunged into a very warm solution of soap, or kali. When the whitlow has been occasioned by a prick, particular care must be taken, that there is no extraneous substance remaining in the puncture.

When the symptoms do not lessen by the fourth day, Richter recommends making an opening in the finger. Even when no fluctuation is discovered, the same surgeon approves of making a crucial incision in the seat of the pain, and, he states, that although no matter may be discharged, the patient always derives infinite relief from the operation. The benefit, he says, may either be imputed to the bleeding, or to the division of the hard tense skin, which compresses the subjacent inflamed parts. Sometimes, the collection of matter can be plainly felt, and, in this case, there can be no hesitation about the place, where the opening should be made. However, it may be proper to remark, that the opening should always be made sufficiently large. When the surgeon makes a small puncture, it very soon closes again, and a repetition of the operation becomes necessary. When opening the abscess is delayed, the theca of the flexor tendons

easily becomes affected, or the matter may make its way to a considerable extent around under the skin. Sometimes, the matter gets through the cutis, by ulceration, and elevates the cuticle, in the form of a pustule. In this case, as soon as the cuticle has been opened, a director should be introduced into the aperture in the skin, and the latter opening be enlarged with a bistoury.

The third species of whitlow seldom affects the last phalanx of the fingers; but, generally, the second, or third one. In this case, Richter enjoins us never to defer making an opening longer, than the third day. If we wait till suppuration happens, we shall wait till the tendons are destroyed, and the use of the finger lost. In the case under consideration, the matter is always of a bad quality, and very small in quantity. A fluctuation in the finger can very seldom be felt. However, in a very few instances, the matter becomes perceptible at the extremity of the finger, or about the finger-joints, but, more often, in the palm of the hand, or near the wrist. In these circumstances, the tendons are in general already destroyed, and a stiffness of the finger and hand is to be apprehended. When the complaint is the consequence of a puncture, the best plan, according to Richter, is at once to enlarge the wound; for, in this sort of case, all other methods are quite unavailing. It is not enough, however, to cut through the skin; the tendinous theca itself must be laid open.

When the pain does not undergo any diminution, after the tendinous sheath has been opened, or, should the pain, after subsiding, recur again, the first opening should be dilated by means of a knife and director. Also, if the patient should experience in any other part of the hand an acute pain, which does not diminish in consequence of this first opening; or if signs of the formation of matter should be observed elsewhere in the hand; an opening should be made there, of sufficient depth to reach through the theca of the flexor tendons. When a collection of matter forms towards the wrist, or the patient feels violent pain in that situation, an opening must also be made there. If an opening should have been already made in the hand, a probe may be introduced into the wound, and another aperture made in an eligible situation by cutting on the end of the instrument. In the same way, Richter advises making an opening in any part of the forearm, where great pain, or the symptoms of suppuration, indicate.

In the fourth kind of whitlow, early incisions, made down to the bone, are the most certain means of obviating the

danger. When such incisions are not made early enough, suppuration takes place, and the bone becomes carious. The cut is to be made in the place, where the pain is most severe. When the first phalanx is affected, the incision may be made in front of the finger; but, when the second, or third, is the seat of the complaint, the opening had better be made on one side. However, in order that the opening may be at all useful, it is absolutely necessary to make it down to the bone. When the incision has been delayed too long, a small quantity of unhealthy matter is usually detected, and the bone is found to be carious. As an exfoliation can hardly be expected in this situation, it is best to remove the diseased piece of bone at once, which can generally be effected without difficulty. When the last phalanx alone is affected, the finger retains its form, with the exception of its end being a little shorter and flatter. When the disease, however, is situated in the third phalanx, Richter thinks it better to amputate the finger, than remove the diseased bone, as the finger, if left, would always remain stiff and unserviceable. (See *Anfangsgr. der Wundarzneykunst*, vol. 7.)

With regard to the treatment of the species of whitlow, named by Mr. Wardrop, *onychias maligna*, all local applications have in many instances proved quite ineffectual, and the part been amputated. The only local treatment, which Mr. Wardrop has ever seen relieve this complaint has been the evulsion of the nail, and afterwards the occasional application of escharotics to the ulcerated surface. I have myself seen a similar plan occasionally succeed, and the applications, which appeared to answer best were arsenical lotions, Plunket's caustic, or a very strong solution of the nitrate of silver. Nothing, however, will avail, till the nail is removed, and its total separation sometimes takes up a good deal of time, unless the patient submit to the great pain of having it cut away.

Mr. Wardrop tried with success the exhibition of mercury in four cases of the *onychias maligna*. The medicine was given in small doses at first, and afterwards increased, so as to affect the gums in about twelve or fourteen days. The sores in general soon assumed a healing appearance, when the system was in this state, and the bulbous swelling gradually disappeared. (See *Medical and Chir. Trans.* Vol. 5, p. 138.)

WOUNDS. A great deal of the subject of wounds has been already considered in the articles, *Gun-shot Wounds*; *Head, Injuries of*; *Hemorrhage*; *Hydrophobia*; *Parotid Duct*; *Sutures*; *Tetanus*; *Throat*; &c.

A wound may be defined to be a recent

solution of continuity in the soft parts, suddenly occasioned by external causes, and generally attended at first with a greater or lesser degree of hemorrhage.

Wounds in general are subject to considerable variety in their nature, degree of danger, facility of cure, and the consequences, which are to be apprehended from them. Some wounds are perfectly trivial, not extending more deeply, than the skin and cellular membrane; while others are more serious, penetrating the muscles, tendons, large blood-vessels, and nerves of importance. There are also certain wounds, which are not confined to the soft parts, but injure even the bones: such are many sabre-wounds, which frequently separate at once both a portion of the scalp and the subjacent part of the skull. Many wounds of the head, chest, and abdomen injure the organs, which are contained in those cavities. In short the varieties, and the degree of danger, attending wounds in general, depend very much upon some of the following circumstances. The extent of the injury; the kind of instrument with which it has been inflicted; the violence, which the fibres of the part have suffered, in addition to their division; the size and importance of the blood-vessels and nerves, which happen to be injured; the nature of the wounded part, in respect to its general power of healing favourably, or not; whether the operations of the system at large, and life itself, can be well supported, or not, while the functions of the wounded part are disturbed, interrupted, or suspended, by the accident; the youth, or old age of the patient; the goodness, or badness of his constitution; and the opportunities, which there may be of administering proper surgical aid, and assistance of every kind.

Wounds are distinguished by surgical writers into several kinds; viz. *incised*, *punctured*, *contused*, *lacerated*, *poisoned*, and *gun-shot wounds*. They also make another equally important division of these cases into *Wounds of the Head, Thorax and Abdomen*.

Of gun-shot wounds, and wounds of the head, an account has already been given. (See *Gun-shot Wounds*, and *Head, Injuries of*.) The other cases I shall now proceed to consider.

INCISED WOUNDS.

As a general observation, we may state, that, *ceteris paribus*, a wound, which is made with a sharp cutting instrument, which is, in short, a mere incision, is attended with less hazard of dangerous consequences, than any other kind of wound whatever. The fibres have only been simply divided; they have suffered

no contusion, nor laceration; they are consequently less likely to inflame so considerably as to suppurate, or slough; and they commonly admit of being united again in a very expeditious manner.

Simple incised wounds for the most part bleed more freely, than contused and lacerated ones, which at first frequently emit no blood at all, although considerable blood-vessels may be injured. But, this circumstance, apparently diminishing the danger of contused and lacerated wounds, is deceitful, and serves rather to render the case in reality more perilous, by inducing the inexperienced practitioner to be off his guard against hemorrhage. Certainly, it often happens, that, on the immediate occurrence of such wounds, there is no bleeding of consequence. However, the side of some large artery having suffered great violence at the time of the accident, it may ulcerate, or slough, a week or ten days afterwards, and an alarming, and even fatal effusion of blood be the result.

This unpleasant occurrence of sudden hemorrhage is particularly apt to occur in cases of gun-shot wounds, which are injuries always attended with a considerable degree of contusion and laceration.

In cases of simple incised wounds, the bleeding, which at once takes place from all the divided vessels, is a source of very useful information to the surgeon, inasmuch as it enables him to judge, what danger is to be apprehended from the hemorrhage, whether the cut vessels are large enough to demand the ligature, or, on the contrary, whether they are such as will cease to bleed, either by slight pressure, or of their own accord.

A surgeon, called to a recent simple incised wound, has three objects which he should endeavour to accomplish, without the least delay. The first, and that which requires his immediate interference, is the bleeding, which must be checked. The second is the removal of all extraneous matter from the surface of the wound. The third object is to unite the opposite sides of the injury.

When the divided vessels are not above a certain size, the bleeding soon spontaneously ceases, and no surgical measures need be taken on this particular account. When the wounded vessels are even somewhat larger, and their situation is favourable for compression with a bandage, it is often advisable to close the wound and apply compresses and a roller, rather than have recourse to ligatures, which always create a certain degree of suppuration. However, though I have made this observation, I should be exceedingly sorry to appear at all against the general preference to ligatures, when-

ever the wounded arteries are above a certain magnitude. In this circumstance, tying the bleeding vessels is the only safe mode of proceeding. When the artery is of considerable size, and its mouth can be readily seen, the most proper instrument for taking hold of it is a pair of forceps. In applying the ligature, the surgeon must take care to pull its ends in such a manner, that the noose will not rise above the mouth of the vessel, and for the purpose of altering the direction of the force employed in tightening the ligature, the ends of the thumbs are generally made use of. The tenaculum is commonly employed for taking up arteries, which are not exceedingly large and distinct.

Very fine ligatures, of sufficient strength, are at present often applied as well to large as small vessels. One half of each ligature should always be cut off, before the wound is closed, and there are some surgeons, who prefer the method of cutting off all the ligature, except what forms the noose immediately round the artery. (*Delppech, Mém. sur la Pourriture d'Hôpital, p. 29; Lawrence in Med. Chir. Trans. Vol. 6, p. 155.*) To the latter plan, however, a few surgeons have adduced objections, particularly Mr. Guthrie, who only admits the utility of it in cases, where the wound will not unite by the first intention; (*On Gun-shot Wounds, p. 94.*) and Mr. Cross, of Norwich. (*See the London Medical Repository, Vol. 7, p. 353.*) The experiments of Mr. Cross tend to the following conclusions:

First; If the wounds do not unite by the first intention, the ligatures may escape with the discharge, without any inconvenience.

Secondly; If common ligatures of twine are cut short, the wound may unite over them, and they may be found in abscesses after an interval of many weeks.

Thirdly; If the finest dentist's silk be employed in the same way, the wound uniting over it, the ligature may be detached from the vessel, and remain buried in an abscess, where it will be found at different periods, from one to seven months; and this may happen, whether the vessel be firmly compressed with a single ligature, or divided between two ligatures, so as to imitate the circumstances, under which vessels are tied after operations.

Fourthly; If Indian silk, fine as hair, be put round a vessel, so as to diminish its diameter, or to effect its obliteration, by just compressing its sides together, it may remain in this situation, without exciting abscess, or producing any inconvenience. The ligature may be thus applied to compress an artery for the cure of aneurism; but, not to secure vessels divided in operations. If a thin ligature be drawn sufficiently tight upon a vessel on the face of a stump to be secure, Mr. Cross is persuaded,

that the extremity of the vessel, which becomes insulated, as it were, must die. (See *London Medical Repository*, Vol. 7, p. 363.) It deserves attention, that the preceding inferences are chiefly founded on experiments made upon asses and dogs.

In the meanwhile, it also merits notice, that the practice continues to be adopted at St. Bartholomew's Hospital to a very great extent, and no ill consequences are remarked from it. It was only the other day, that my friend Mr. Lawrence informed me, he had never seen any inconvenience from the method, except in one solitary instance. In this case, one of the arteries of the wrist had been tied with a fine ligature, which was cut off close to the knot. The wound healed very well; but, there remained afterwards a small, indolent, lump, which caused no particular annoyance, and from the little swelling a minute portion of ligature was either discharged, or extracted, I forget which.

However, I need not expatiate on the mode of tying arteries, as the subject is fully considered in other parts of this Dictionary. See *Aneurism, Hemorrhage, Ligature, Surgery*, &c.

The bleeding having been suppressed, the next object is to remove any extraneous matter, such as dirt, bits of glass, clots of blood, &c. from the surface of the wound. Were this circumstance neglected, the plan of uniting the opposite sides of the cut by the adhesive inflammation, or by what is more frequently termed, union by the first intention, would in general be frustrated.

As soon as the foregoing indications have been attended to, the surgeon must approximate the lips of the wound, put them in contact, and take proper precautions for keeping them in this state, until they have firmly grown together. The sides of incised wounds are kept in a state of apposition by the aid of adhesive plaster, a proper position, the pressure of a roller, and, in a few particular instances, by the employment of sutures.

With respect to sutures, as they create pain and irritation, they ought never to be employed when the parts can be kept in contact without them. Certain cases, however, require them, and it is admitted by every experienced surgeon, that in sabre-wounds of the ears, eyelids, nose, and lips, it is proper to use them. (See *Assalini's Manuale di Chirurgia, Parte Seconda*, p. 10.) An account of the several kinds of sutures, with remarks on their employment, will be found in the article *Sutures*.

The best and most common method of keeping the surfaces of divided parts in contact is by means of strips of adhesive plaster. At the time, when they are to be applied, the surgeon should put the wounded parts in such a position, as shall render

them capable of being brought into a state of apposition with most facility. With this view, a position should generally be chosen, which relaxes the skin and subjacent muscles. An assistant should then place the edges of the wound as evenly together as possible, and hold them in this state, until the surgeon has secured them in this condition by strips of adhesive plaster, applied across the line of the wound. In general, it is deemed advisable to leave a small interspace of about a quarter of an inch between each two strips of plaster, by which means the matter cannot be confined in case of suppuration. Over these first strips, lint is to be applied, and kept in its place with other pieces of adhesive plaster. Then, if necessary, a pledget and compresses are to be put on the part, and, lastly, the bandage, or roller, is to be applied.

In this manner, the fresh-cut surfaces are brought into contact, and to preserve them quietly in this state, is the next great aim, which the surgeon should have in view. The wounded part should be laid in the posture, which was found the most favourable for approximating the sides of the cut, at the time of applying the dressings, and the patient should be directed to keep the part in a perfectly quiet state.

When attention is paid to these circumstances, it often happens, that the two opposite surfaces of the wound grow together again in the course of forty-eight hours, without the occurrence of the least degree of suppuration. The process, by which this desirable event is accomplished, is well known among surgeons, by the name of *union by the first intention*. Besides the advantage of the cure being effected in this way with the greatest expedition possible, there is still another thing much in favour of constantly promoting this method of healing wounds, which is, that the scar is much less, than after any other plan, and the part is covered with original skin, which is always much stronger, than any which can be formed as a substitute for it.

It is wonderful, with what celerity union by the first intention takes place under favourable circumstances. In the course of three days, the large wound, made in the operation of amputation, is frequently all healed, except just where the ligatures are situated.

When the two sides of the wound have been brought together, before the oozing of blood has entirely ceased, Mr. Hunter conceives, that blood itself becomes the first bond of union; but, on this point, Professor Thomson, of Edinburgh, entertains a doubt; and all practical surgeons agree, that the presence of blood is more likely to prevent, than promote, the union

of the parts. In other instances, what Mr. Hunter called the adhesive inflammation occurs. In this process, coagulating lymph either issues from the half-closed mouths of the vessels, or from the surface of the opened cells of the cellular substance. This becomes the first uniting medium, and, very soon afterwards, in some inexplicable manner, a vascular intercourse is established between the opposite sides of the wound.

The power, which parts of the animal body have, of growing together in the above manner, is strikingly evinced by the possibility of removing a part of one body, and then uniting it to some part of another. In this latter case, there can be no assistance given to the union on one side, since the detached part, as Mr. Hunter observes, can hardly do more, than just preserve its own living principle, and accept of union. In this way, says the same writer, the spurs of the young cock can be made to grow on his comb, or on that of another cock; and its testicles, after having been removed, may be made to unite to the inside of any cavity of an animal.

Every one initiated in surgery has heard of the feats of Taliacotius, Garengeot, and others, who are said to have succeeded in effecting the union of parts, which were completely severed from the body. Several other not less extraordinary performances by modern surgeons have come to my ears. Indeed, the well-known practice of transplanting the teeth; the experiments of Duhamel and Hunter; and the number and respectable character of the testimonies upon this subject, fully convince me of the occasional success, which may attend the endeavour to bring about such an union. Experience also fully proves the frequent success, which attends an endeavour to unite a part, which retains only the slight connexion of a small piece of flesh, or even a few fibres. My friend, Mr. Lawrence, lately had a case, which illustrates the truth of this statement. A man, on the top of a stage coach, was carried under a gateway, which did not leave sufficient room for him to pass without injury, and his head was so much wounded, that one of his ears was entirely separated, with exception of an attachment by a trivial piece of integuments. Mr. Lawrence assented to the man's wish of not having the separation completed, and fixed the part in its situation with a few sutures. The consequence was that the ear soon united again, and the patient escaped all disfigurement.

Mr. John Bell describes the process of adhesion to be this: either the arteries of the opposite surfaces inosculate mouth to mouth, or rather each cut-surface throws out a gluten; the gluten fills up the intermediate space; into that gluten, the lesser arteries of each cut-surface extend them-

selves, and it is thus, perhaps, by the generation of a new intermediate substance, that the continuity and entireness of the part are so quickly restored. If any one point fail to adhere, there the wound must run into suppuration; because, says Mr. J. Bell, at that point there is a separation of parts, which is equivalent to a loss of substance.

The same writer observes, that there are, no doubt, accidents, both of the constitution and the wound, which will prevent adhesion. If the patient be of a bad habit of body; if he be lying in a foul hospital, in the midst of putrid sores, and breathing a contagious air; if he be ill of a fever, or flux, or any general disease; then the properties of the body being less perfect, the wound will not adhere. Mr. J. Bell also notices, that, if the wound be foul, made with a poisoned weapon, or left with foreign bodies lodged in it; or if a considerable quantity of blood be poured out into the cavity of the wound; or if there be a wounded lymphatic, or a wounded salivary duct, a wounded intestine, or a bleeding artery or vein, the immediate adhesion of the whole of the wound may be prevented. However, I cannot help remarking, that, though Mr. John Bell, in imitation of most surgical writers, sets down the wound of a lymphatic, as preventive of the union of wounds, I cannot say, that I ever saw such an effect imputable to the cause just mentioned. Also, when an artery, or vein is cut, and requires being tied, the adhesion of the wound would only be prevented just where the ligature lies.

There is no wound, observes Mr. John Bell, in which we may not try with perfect safety to procure this adhesion; for, nothing can agree better with one surface of the wound, than the opposite one, which has been just separated from it. They may immediately adhere together, and even if they should not do so, no harm is done, and the wound will yet suppurate as favourably, as if it had been roughly dressed with dry caddis, or some vulnerary balsam, or acrid ointment. If one part should suppurate, while one half adheres, then, says Mr. John Bell, one half of our business is done. In short, this simple duty of immediately closing a wound is both natural and safe. (*Discourses on the Nature and Cure of Wounds, Vol. 1.*)

Upon this interesting topic of the advantages of union by the first intention, the most enlightened surgeons of all Europe now begin to entertain only one opinion. The practice is generally adopted both in the treatment of accidental cuts, and of the wounds resulting from surgical operations. Thus Assalini, one of the best modern surgeons in Italy, begins his *Manual of Surgery* with the following axiom: "Wounds and injuries of the soft parts, produced by cutting instruments, from the trifling

wound of a vein, made for the purpose of discharging a few ounces of blood, to the incision in the uterus for the extraction of the foetus, inclusively, should all be united by the first intention." (See *Manuale di Chirurgia del C. Assalini; Discorso Primo. Milano, 1812.*)

British surgeons have, indeed, been accused by M. Roux of indiscriminate partiality to the plan of uniting all incised wounds by the first intention, and his countryman M. Larrey has wished the method to be discontinued after amputation, in order (as he states) to lessen the chance of tetanus. But, the exceptions, which these surgeons wish to make, are few, and few as they are, they are not likely to be established, since several of the circumstances, alleged as reasons for limiting so beneficial a practice, are hypothetical, and far from being clearly proved.

Sometimes, the attempt to procure an union by the first intention fails, even in cases of incised wounds; but, in this circumstance, no harm arises from the kind of practice, which has been followed. The case, in fact, now falls into nearly the same state, as would have occurred, had no attempt at union been made at all. The patient has taken the chance of a quicker mode of cure; but, he has not been successful, and he must now be cured by a process, which on account of its slowness he at first wished to avoid. It is to be observed, also, that union by the first intention, if not spoiled by sutures, rarely fails so completely, that there is not a partial adhesion of some points of the wound. The moment, when we observe pain, inflammation, and swelling of the wound, a separation or gaping of its lips, the stitches tense (when these have been used), and the points, where the stitches pass, particularly inflamed, Mr. John Bell advises us to undo the bandages, draw out the sutures, and take away every thing, which acts like a stricture on the wound. These prudent measures, he observes, may abate the rising inflammation, and prevent the total separation of the skin, while an endeavour may still be made to keep the edges of the wound tolerably near each other by the more gentle operation of sticking-plasters.

However, when the inflammation rises still higher, and it is evident that a total separation of the sides of the wound cannot be avoided, the above author recommends leaving the parts quite loose, and applying a large soft poultice; for, says Mr. John Bell, should you, in this critical juncture, persist in keeping the parts together with sutures, the inflammation, in the form of erysipelas, would extend over the whole limb, attended with a fetid and bloody suppuration. After the wound has got into a favourable state, another attempt may now be made to bring the edges near

each other, not with sutures, but, strips of adhesive plaster, or the gentle application of a bandage.

Mr. John Bell concludes with remarking, that the suppuration, production of granulations, and all that follows, are the work of nature. The only thing, that the surgeon can usefully do, is to take care of the health. When the wound does not suppurate favourably, the discharge generally becomes profuse, thin and gleety. This state is to be amended by bark, wine, rich diet, and good air.

I shall conclude this subject of union by the first intention with an extract from the writings of Mr. Hunter, who observes that

"It is with a view to this principle of union, that it has been recommended to bring the sides (or lips) of wounds together; but as the natural elasticity of the parts makes them recede, it has been found necessary to employ art for that purpose. This necessity first suggested the practice of sewing wounds, and afterwards gave rise to various inventions in order to answer this end, such as bandages, sticking-plasters, and ligatures. Among these, the bandage commonly called the uniting bandage is preferable to all the rest, where it can be employed; but its application is very confined, from being only adapted to parts where a roller can be used. A piece of sticking-plaster, which has been called the dry suture, is more general in its application than the uniting bandage, and is therefore preferable to it on many occasions.

"I can hardly suppose (says Mr. Hunter) a wound, in any situation, where it may not be applied, excepting penetrating wounds, where we wish the inner portion of the wound to be closed equally with the outer, as in the case of hare-lip. But even in such wounds, if the parts are thick, and the wound not large, the sides will seldom recede so far as to make any other means necessary. The dry suture has an advantage over stitches, by bringing a larger surface of the wound together, by not inflaming the parts to which it is applied, and by neither producing in them suppuration nor ulceration, which stitches always do. When parts, therefore, can be brought together, and especially where some force is required for that purpose, from the skin not being in large quantity, the sticking-plaster is certainly the best application. This happens frequently to be the case after the removal of tumours, in amputation, or where the sides of the wound are only to be brought together at one end, as in the hare-lip; and I think the difference between Mr. Sharp's cross-stitch, after amputation, as recommended in his *Critical Enquiry*, and Mr. Allanson's practice, shews strongly the superiority of the sticking-plaster (or dry suture). In those parts of the body where the skin recedes more

than in others, this treatment becomes most necessary; and as the scalp probably recedes as little as any, it is therefore seldom necessary to apply any thing in wounds of that part; the practice will certainly answer best in superficial wounds, because the bottom is in these more within its influence.

"The sticking plasters should be laid on in strips, and these should be at small distances from each other, viz. about a quarter of an inch at most, if the part requires close confinement; but when it does not, they may be at greater distances. This precaution becomes more necessary if the bleeding is not quite stopped; there should be passages left for the exit of blood, as its accumulation might prevent the union, although this does not always happen. If any extraneous body, such as a ligature, should have been left in the wound, suppuration will take place, and the matter should be allowed to vent at some of those openings, or spaces, between the slips of plaster. I have known a very considerable abscess formed in consequence of this precaution being neglected, by which the whole of the recently united parts has been separated.

"The interrupted suture, which has generally been recommended in large wounds, is still in use, but seldom proves equal to the intention. This we may reckon to be the only one that deserves the name of suture; it was formerly used, but is now in a great measure laid aside in practice, not from the impropriety of uniting parts by this process, but from the ineffectual mode of attempting it. In what manner better methods could be contrived, I have not been able to suggest. It is to be understood, that the above methods of bringing wounded parts together, in order to unite them, are only to be put in practice in such cases as will admit of it; for if there was a method known, which in all cases would bring the wounded surfaces into contact, it would, in many instances, be improper, as some wounds are attended with contusion, by which the parts have been more or less deadened; in such cases, as was formerly observed, union cannot take place according to our first principle, and therefore it is improper to attempt it.

"In many wounds, which are not attended with contusion, when we either know, or suspect, that extraneous bodies have been introduced into the wound, union by the first intention should not be attempted, but they should be allowed to suppurate, in order that the extraneous matter may be expelled. Wounds, which are attended with laceration, although free from contusion, cannot always be united by the first intention, because it must frequently be impossible to bring the

external parts, or skin, so much in contact, as to prevent that inflammation which is naturally produced by exposure. But even in cases of simple laceration, where the external influence is but slight, or can be prevented (as we observed in treating of the compound simple fracture) we find that union by the first intention often takes place; the blood, which fills up the interstices of the lacerated parts, having prevented the stimulus of imperfection in them, and prevented suppuration, may afterwards be absorbed.

"Many operations may be so performed as to admit of parts uniting by the first intention; but the practice should be adopted with great circumspection: the mode of operating with that view, should in all cases be a secondary, and not a first consideration, which it has unluckily been too often among surgeons. In cases of cancer, it is a most dangerous attempt at refinement in surgery.

"In the union of wounded parts by the first intention, it is hardly or never possible, to bring them so close together at the exposed edges, as to unite them perfectly by these means; such edges are therefore obliged to take another method of healing. If kept moist, they will inflame as deep between the cut surfaces as the blood fails in the union, and there suppurate and granulate; but if the blood be allowed to dry and form a scab between, and along the cut edges, then inflammation and suppuration of those edges will be prevented, and this will complete the union, as will be described by-and-by.

"As those effects of accidental injury, which can be cured by the first intention, call up none of the powers of the constitution to assist in the reparation, it is not the least affected or disturbed by them; the parts are united by the extravasated blood alone, which was thrown out by the injury, either from the divided vessels, or in consequence of inflammation, without a single action taking place, even in the part itself, except the closing or inosculation of the vessels; for the flowing of the blood is to be considered as entirely mechanical. Even in cases where a small degree of inflammation comes on, it is merely a local action, and so inconsiderable, that the constitution is not affected by it; because it is an operation to which the powers belonging to the parts themselves are fully equal. The inflammation may produce a small degree of pain, but the operation of union gives no sensation of any kind whatever." (*Hunter on the Blood, Inflammation, and Gun-shot Wounds.*)

CONTUSED AND LACERATED WOUNDS.

Lacerated wounds are those, in which the fibres, instead of being divided by a

cutting instrument, have been torn asunder by some violence, capable of overcoming their force of adhesion. The edges of such wounds, instead of being straight and regular, are jagged and unequal.

The term *contused* is applied to those wounds, which are occasioned by some blunt instrument, or surface, which has violently struck a part of the body.

These two species of wounds greatly resemble each other, and as they require nearly the same kind of treatment, writers usually treat of them together.

Lacerated, and contused, wounds differ from simple incised ones in appearing, at first view, much less alarming, than the latter, while, in reality, they are infinitely more dangerous. In simple cut wounds, the retraction of the parts, and the hemorrhage, are generally much more considerable, than in a lacerated wound of the same size. However, notwithstanding these circumstances, they commonly admit of being healed with by far the greatest ease. It is worthy of particular notice, that lacerated and contused wounds are not in general attended with any serious effusion of blood, even though large blood-vessels may be injured. I say, in general, because in the year 1813, I saw a soldier, whose death was occasioned by a sudden effusion of a very large quantity of blood from the internal jugular vein, which vessel had been injured by a musket-ball, that first entered the integuments behind the mastoid process, and passed obliquely downwards and forwards towards the sternum. The blood did not issue externally; but, formed betwixt the integuments and the trachea, a large dark-coloured swelling, which produced almost immediate suffocation. At the memorable siege of Saragossa, Professor Assalini saw a surgeon, whose left carotid artery had been injured by a musket-ball, perish of hemorrhage in a few seconds. (See *Assalini's Manuale di Chirurgia*, p. 32, Milano, 1812.)

In most cases, however, there is little, or no hemorrhage from lacerated and contused wounds, and it is a circumstance, which often leads inexperienced practitioners to commit great mistakes, by inducing them to promise too much in the prognosis, which they make. Surgeons versed in practice, however, do not allow themselves to be deceived by the absence of hemorrhage, and, in proportion as there is little bleeding, they apprehend that the violence, done to the fibres and vessels has been considerable. What is it, but the contused and lacerated nature of the wound, that prevents hemorrhage from the umbilical arteries, when animals divide the navel-string with their teeth? Whole limbs have frequently been torn from the body, without any hemorrhage of consequence taking place.

Cheselden has described, in the *Philosophical Transactions*, a very remarkable case, in which a man's arm was suddenly torn from his body. Samuel Wood, a miller, had round his arm a rope, which got entangled with the wheel of a mill. He was lifted off the ground, and then stopped by a beam, which prevented his trunk from passing further; at this instant, the wheel, which was moving with immense force, completely tore, and carried away, his arm and scapula from his body. The appearance of a wound, occasioned in this manner, must of course be horrible, and the first idea, thence arising, must naturally be that the patient cannot possibly survive. Samuel Wood, however, escaped with his life. The limb had been torn off with such velocity, that he was unaware of the accident, till he saw his arm moving round on the wheel. He immediately descended by a narrow ladder from the mill, and even walked some paces, with a view of seeking assistance. He now fell down from weakness. The persons who first came to his assistance, covered the wound with powdered sugar. A surgeon, who afterwards arrived, observing that there was no hemorrhage, was content with bringing down the skin, which was very loose, so as to make it cover the surface of the wound. For this purpose, he used two cross-stitches. The patient was conveyed, the next day, to St. Thomas's Hospital, and put under the care of Mr. Fern, who was then the head surgeon of that charity. This practitioner employed the means usually resorted to, with a view of preventing the bad symptoms to be apprehended in this sort of case. The first dressings came away without any bleeding; no alarming consequences ensued; and the patient got completely well in the course of a couple of months.

When the arm was examined, it was found, that the muscles, inserted into the scapula, were torn through near their insertions; while other muscles, arising from this bone, were carried away with it. The skin, covering the scapula, had remained in its natural situation, and seemed as if it had been divided precisely at the insertion of the deltoid muscle.

In La Motte's *Traité des Accouchemens*, may be found an account of a little boy, who, while playing near the wheel of a mill, got his hand, fore-arm, and arm, successively entangled in the machinery, and the limb was violently torn away at the shoulder joint, in consequence of the lad's body not being able to pass in the direction, in which the arm was drawn. The bleeding was so trivial, that it was stopped with a little lint, and the boy very soon recovered.

In the fifth volume of the *Edinburgh Medical Commentaries*, may also be per-

used the history of a child, three years and a half old, which had its arm torn off by the wheel of a mill. Mr. Carmichael, who saw the child about an hour after the accident, found it almost in a dying state, with cold extremities, small faltering pulse, and all the right side of the body convulsed. However, there had been hardly any bleeding. The arm had been broken about an inch and a half above the elbow; the stump had a very dreadful appearance; all the soft parts were in a contused and lacerated state, and the humerus was laid bare as high as the articulation, which was itself exposed. The skin and muscles were lacerated to a much greater extent, and in different directions. The remainder of the humerus was removed from the shoulder-joint by amputation, only as much skin and muscle being left, as was sufficient to cover the wound. The child got completely well in two months.

In the second volume of the *Mémoires de l'Académie de Chirurgie*, is an account of a leg being torn away at the knee-joint by a cart-wheel. The patient was a boy, about nine or ten years of age. This accident, like the foregoing ones, was accompanied with no hemorrhage. The lower portion of the os femoris, which was exposed, was amputated, together with such portion of the soft parts, as was in a contused and lacerated state. The patient experienced a perfect recovery.

The preceding cases strikingly confirm the observation, which I have already made, in regard to the little bleeding, which usually arises from contused and lacerated wounds.

In these instances, the pain is also in an inverse ratio to the cause of the accident: it is generally very severe, when the wound is only moderately contused; and, on the other hand, the patient scarcely suffers any pain at all, where there has been so violent a degree of contusion, as at once to destroy the organization of the nerves of the part.

When the bruised fibres have not been exceedingly injured, the part suppurates; but, such portions of the wound, as have suffered greater violence, inevitably die, and are cast off in the form of sloughs. Granulations are afterwards formed, and the breach of continuity is repaired by the process of cicatrization. (See *this word*.)

When a still greater degree of violence has been done to the parts, and, especially, when arteries of a certain magnitude have been injured, a mortification is too frequently the consequence. However, if the constitution is good, and the mischief is not too extensive, the case may still end well. But, in other instances, the event is always alarmingly dubious; for, the mischief is then not limited to the wounded

parts, which have suffered the greatest degree of contusion; but, too frequently extends over such parts, as were not at all interested by the wound itself.

The mortification, arising directly from the impaired organization of parts, is not what is the most alarming circumstance. The most dangerous kind of mortification is that, which is apt to originate from the violent inflammation, occasioned by the accident. This consequence demands the utmost attention on the part of the surgeon, who must let no useful means be neglected, with a view of diminishing the inflammation, before it has attained so high a pitch, as to induce fatal effects. He should not be afraid of letting the wound bleed a little, if it should be disposed to do so in the first instance. The edges of the wound should then be approximated with a few strips of sticking-plaster, so as to lessen the extent of the exposed surface: but, no sutures are proper. Indeed, the plan of diminishing the exposed surface of a contused wound with strips of adhesive plaster is not invariably right; because their application creates a degree of irritation, which proves hurtful. The method is chiefly advisable, when there is a large loose flap of skin, which can be conveniently brought over the wound. In other cases, it is best to leave the parts free, uncompressed, and unconfined with any adhesive plaster, because, if it were applied, its irritation would do harm, and could not possibly procure any union of the parts. Under the most favourable circumstances, hardly any part of the wound can be expected to unite by the first intention; the whole, or the greater part of it will necessarily suppurate, after the detachment of the sloughs. The surface will then granulate, new skin will form, and the part heal just like a common wound. Perhaps, until the sloughs have separated, the best application is a soft poultice, which should be put on cold, lest it bring on too great an oozing of blood.

Nothing, indeed, is so proper for checking any tendency to hemorrhage as cold applications, which are also the most effectual in preventing and diminishing the great degree of inflammation, which is one of the most dangerous consequences of this description of wounds.

No surgical writer, I think, has given more rational advice respecting contused wounds, than that published by Professor Assalini. In general, says he, the treatment of contused wounds, whether these be simple and slight, or complicated and severe, requires the active employment of debilitating means, in order to prevent inflammation. Cold water, and ice; and general and topical bleeding; are the things usually resorted to with success. Vulnerary lotions, camphorated spirit, and other

spirituous applications, are improper, and if their pernicious effects are not always very evident, it is only because the contused injuries have been trifling, and in their nature perfectly easy of cure. In these cases, as well as in those of extravasations and glandular swellings, Assalini gives a preference to cold applications. The internal remedies and regimen, (says he) should also be adapted to the condition of the patient. A cannon-ball, at the end of its course, may come into contact with a limb, and fracture the bones, while the integuments have the appearance of being uninjured. Such cases are often attended with dreadful mischief in the soft parts around the bone, which generally sphacelate. This is an accident for which immediate amputation is mostly indispensable (see *Gun-shot wounds*); but if any thing be capable of preventing inflammation and gangrene, it is an active debilitating plan of treatment, assisted with cold applications to the injured part. The internal and external use of stimulants is in such cases approved of by many surgeons. But, Assalini prefers considering the state of the injured limb, just like what it is when affected with frost; and he thinks that the employment of stimulants will necessarily produce the same effect as caloric prematurely applied to parts deadened with cold. On the contrary, from the outward employment of ice and cold lotions in these cases, and in contused injuries in general, he has seen the greatest benefit derived.

Assalini conceives, that reason will be found to support this practice. The operation of cold, he says, retards the course of the blood, which meeting with only damaged vessels, augments the extravasation as it continues to flow. By lessening the temperature of the part, cold applications likewise diminish the danger of inflammation and sphacelus, at the same time that they have the good effect of making the suppuration, which must ensue, less profuse, than it would be, had not the extravasation of blood, and violence of the inflammation, been lessened by such cold applications, and a lowering plan of treatment.

Why, says Assalini, should not this method, which is so generally adopted to prevent the effects of concussion of the brain after blows on the head, be for analogous reasons employed in examples of extravasation and commotion in other parts of the body? (See *Assalini's Manuale di Chirurgia, Parte Prima, p. 17.*) Cold applications, however, in cases of contused wounds, are chiefly to be preferred, for the first day or two, in order to check the increase of extravasation, and inflammation. After this period, I give a decided preference to an emollient linseed poultice, which will

be found the most easy dressing during those processes, by which the sloughs are detached, the surface of the wound cleansed, and the origin of granulations established. When these changes have happened, the remaining sore is to be treated on the same principles as ulcers in general. See *Ulcer*.

PUNCTURED WOUNDS.

A punctured wound signifies one, that is made with a narrow-pointed instrument, the external orifice of the injury being small and contracted, instead of being of a size proportionate to its depth. A wound, produced by the thrust of a sword, or bayonet, affords us an example of a punctured wound.

Wounds of this description are in general infinitely more dangerous, than incised ones, notwithstanding the latter have the appearance of being by far the most extensive. The greatest degree of danger, in cases of punctured wounds, always depends on the additional injury, and rough violence, which the fibres have suffered, besides being divided. Some of the disagreeable consequences, apt to follow, are also to be imputed to the frequent great depth, to which punctured wounds are liable to extend, in consequence of which circumstance, important parts and organs are often injured. These cases are likewise less easy of cure, owing to the difficulty of extracting any extraneous substances, which may happen to be lodged in the wound. All punctured wounds, and stabs are at the same time dangerous, inasmuch as they are particularly liable to be followed by a great deal of inflammation, fever, deep-seated abscesses, sinuses, &c.

A strange notion seems to pervade the writings of many systematic authors, that all the danger and disagreeable consequences of punctured wounds are entirely owing to the narrowness of the orifice, which prevents suitable applications to the bottom of such wounds. Hence, it is absurdly recommended to dilate the opening of every stab, with a view, as is generally added, of converting the accident into a simple incised wound. Some of these writers are advocates for making the dilatation with a cutting instrument, while others, with equal absurdity, advise enlarging the opening with tents.

Certain authors regard a punctured wound, as a recent sinus, and, in order to make the inner surfaces unite, they recommend exciting a degree of inflammation in them, either by means of setons, or injections.

In the earliest edition of *The First Lines of the Practice of Surgery*, I have taken particular pains to expose the folly and error, which prevail in most writings on this part of practice. In the above work, I

have remarked, that, certainly, if the notion were true, that an important punctured wound, such as the stab of a bayonet, is actually changed into a wound partaking of the mild nature of an incision, by the mere enlargement of its orifice, the corresponding practice would be highly commendable, however painful it might be. But the fact is otherwise; the rough violence done to the fibres of the body by the generality of stabs, is little likely to be suddenly removed by an enlargement of the wound. Nor can the distance, to which a punctured wound frequently penetrates, and the number and nature of the parts injured by it, be at all altered by such a proceeding. These, which are the grand causes of the collections of matter that often take place in the cases under consideration, must exist, whether the mouth and canal of the wound be enlarged or not. The time when incisions are proper, is, when there are foreign bodies to be removed, abscesses to be opened, or sinuses to be divided. To make painful incisions sooner than they can answer any end, is both injudicious and hurtful. They are sometimes rendered quite unnecessary, by the union of the wound throughout its whole extent, without any suppuration at all.

Making a free incision in the early stage of these cases, undoubtedly seems a reasonable method of preventing the formation of sinuses, by preventing the confinement of matter, and, were sinuses an inevitable consequence of all punctured wounds, for which no incisions had been practised at the moment of their occurrence, it would undoubtedly be unpardonable to omit them. Fair, however, as this reason may appear, it is only superficially plausible, and a small degree of reflection soon discovers its want of real solidity. Under what circumstances do sinuses form? Do they not form only where there is some cause existing to prevent the healing of an abscess? This cause may either be the indirect way, in which the abscess communicates externally, so that the pus does not readily escape; or it may be the presence of some foreign body, or carious bone; or, lastly, it may be an indisposition of the inner surface of the abscess, to form granulations, arising from its long duration, but removeable by laying the cyst completely open to the influence of the air. Thus it becomes manifest, that the occurrence of suppuration in punctured wounds, is only followed by sinuses in cases, in which the surgeon neglects to procure a free issue for the matter, after its accumulation; or in which he neglects to remove any extraneous bodies. But, as dilating the wound at first can only tend to augment the inflammation, and render the suppuration more extensive, it ought never

to be practised in these cases, except for the direct objects, of giving free exit to matter already collected, and of being able to remove extraneous bodies palpably lodged. I shall once more repeat, that it is an erroneous idea, to suppose the narrowness of punctured wounds so principal a cause of the bad symptoms, with which they are often attended, that the treatment ought invariably to aim at its removal.

Recent punctured wounds have absurdly had the same plan of treatment applied to them, as old and callous fistulæ. Setons and stimulating injections, which, in the latter cases, sometimes act beneficially by exciting such inflammation as is productive of the effusion of coagulating lymph, and of the granulating process, never prove serviceable when the indication is to moderate an inflammation, which is too apt to rise to an improper height. The counter-opening, that must be formed in adopting the use of a seton, is also an objection. However, what good can possibly arise from a seton in these cases? Will it promote the discharge of foreign bodies, if any are present? By occupying the external openings of the wound, will it not be more likely to prevent it? In fact, will it not itself act with all the inconveniences and irritation of an extraneous substance in the wound? Is it a likely means of diminishing the immoderate pain, swelling, and extensive suppuration, so often attending punctured wounds? It will undoubtedly prevent the external openings from healing too soon; but cannot this object be effected in a better way? If the surgeon observes to insinuate a piece of lint into the sinus, and pass a probe through its track once a day, the danger of its closing too soon will be removed.

The practice of enlarging punctured wounds by incisions, and of introducing setons, is often forbidden by the particular situation of these injuries.

In the first stage of a punctured wound, the indication is to guard against the attack of violent inflammation. When no considerable quantity of blood has been lost, general and topical bleeding should be practised. In short, the antiphlogistic plan is to be followed. As no man can pronounce, whether such wounds will unite, or not, and as no harm can result from the attempt, the orifice ought to be closed, and covered with simple dressings. Cold applications in such cases are also highly commendable. Whether gentle compression might be made to promote the adhesive inflammation, or not, may be doubtful: I confess, that I should not have any reliance upon its usefulness. Perfect quietude is to be observed. When the pain is very severe, opium is to be administered.

Sometimes, under this treatment, the surgeon is agreeably surprised to find the

consequent inflammation mild, and the wound speedily united, by the first intention. "Numerous are the examples of wounds, which penetrate the large cavities, being healed by the first intention, that is, without any suppuration. Even wounds of the chest itself, with injury of the lungs, (continues an experienced military surgeon and professor) ought to be united by the first intention." (*Assalini, in Manuale di Chirurgia, parte Secunda, p. 13.*) More frequently, however, in cases of deep stabs, the pain is intolerable; and the inflammatory symptoms run so high as to leave no hope of avoiding suppuration. In this condition, an emollient poultice is the best local application; and, when the matter is formed, the treatment is like that of abscesses in general. (See *Suppuration.*)

POISONED WOUNDS, BITE OF THE VIPER, &c.

If we exclude from present consideration the bites of mad dogs, and other rabid animals, which subject is fully treated of in the article *Hydrophobia*, wounds of this description are not very common in these islands. Pricks of the hand sometimes occur in dissecting bodies; they are a species of poisoned wound, frequently causing considerable pain and irritation in the course of the absorbents of the limb; swelling and suppuration of the lymphatic glands of the arm, or axilla; and severe fever and constitutional irritation. An instance of the fatal consequences of such an injury must still be fresh in the recollection of the profession. (See *Case in the London Medical Repository, Vol. 7, p. 288.*)

In many instances, however, surgeons wound their fingers in dissecting bodies, and no particular ill consequences ensue. The healthy and robust are said to suffer less frequently after such accidents, than persons, whose constitutions have been weakened by hard study, excesses, pleasure, or some previous disease. It is remarked, also, that pricks of the fingers, met with in opening the bodies of persons, who have died of contagious diseases, and where a virus, or infectious matter might be expected to exist in such bodies, do not communicate the infection. Doubtless, (observes Richerand) the activity of those animal poisons, from which the venereal and several other diseases arise, is extinguished with life. (*Nosographie Chir. T. 1, p. 102, 103, Edit. 4.*)

With regard to the treatment of the pricks of dissecting scalpels, the surgeons of the continent recommend the immediate cauterization of the little wound with a grain of caustic potassa, or the liquid muriate of ammonia. Tonic remedies, particularly wine, is to be prescribed, and great attention paid to emptying the bowels.

The stings of bees, wasps, and hornets,

are also poisoned wounds, though it is true they are seldom important enough to require the assistance of a surgeon. The hornet is not to be found in Scotland; but, it is an inhabitant of several of the woods in England. Its sting, which is more painful, than that of a bee, or wasp, is not however often the occasion of any serious consequences. The stings of all these insects are attended with a sharp pain in the part, very quickly succeeded by an inflammatory swelling, which after a short time generally subsides of itself. It has been lately observed, that the pain of the stings of venomous insects, like the bee, depends less upon the introduction of the sting into the part, than upon that of the venomous fluid. The experiments of Professor Duméril tend to prove, that, when the little poison-bladder, situated at the base of the sting, has been cut off, a wound with the sting then produces no pain. The poison, flows from the vesicle through the sting at the instant when this passes into the flesh. The exact nature of this venomous fluid is not known. It is said to be neither acid, nor alkaline. When applied to mucous surfaces, or even to the conjunctiva of the eye, it causes no disagreeable sensation; but, when it is introduced into the skin, by means of a needle, it immediately excites very acute pain.

Oil, honey, spirits of wine, the juice of the plantain, and a variety of other local applications, have been extolled as specifics for the relief of the stings of insects. Modern experience, however, does not sanction their claim to this character. In fact, none of these applications either neutralize the poison, or appease with superior efficacy the pain of the sting.

These cases should all be treated on common antiphlogistic principles, and the most rational plan is to extract the sting, taking care in the first instance to cut off the little poison-vesicle with scissars, lest in the attempts to withdraw the sting, more of the virus be compressed into the part. The stung part should then be immersed for a time in ice-cold water, and afterwards enveloped in linen wet with a lotion of acetite of lead. Were the inflammation to exceed the usual degree, leeches and aperient medicines would be proper. In short, as there is no specific for the cure of these cases, they are to be treated by antiphlogistic means.

With regard to the bites of serpents, those inflicted by the rattle-snake of America, and the cobra de capello of the East-Indies, are the most speedily mortal. Indeed, this is so much the case, that there is scarcely time to apply any remedy, although it be at hand the very moment, when the bite is received. Mr. Catesby, in the Preface to his *Natural History of Carolina*, informs us, that the Indians,

who, by their constant wanderings in the woods, are liable to be bit by those venomous animals, know, as soon as they receive the injury, whether it will prove mortal or not. If it be on any part at a distance from large blood-vessels, or where the circulation is not vigorous, they apply their remedies; but, if any vein, of considerable magnitude, happens to be hurt, they quietly resign themselves to their fate, knowing that nothing can then be of service. It is not well known what the remedies are, on which they chiefly depend. Seneka root and volatile alkali, are among the number; and, more particularly, strong doses of arsenic, as we shall have occasion to notice again.

If we put out of consideration animals affected with rabies, the viper inflicts the worst poisoned wound, ever met with in these islands. In fact, it is an animal, which inserts into the part, which it bites, a poison, that is capable of exciting very serious consequences. The jaws of the viper are furnished with teeth, two of which in the upper jaw are very different from the rest. These, which are about three lines long, are covered for about two thirds of their length with a membranous coat, or sheath; they have a bent, or curved shape; and are articulated with the jaw-bone. They admit of being moved from before backwards, and are so disposed, that they lie down with their points turned backwards, when the animal is tranquil, and his mouth shut; but, they are instantaneously projected forwards, when he is irritated, and about to bite. These curved fangs contain canals, which terminate by a very narrow fissure, on their convex sides, a little way from their points. The rest of each of these fangs is very hard and solid; and the canal is usually filled with a transparent, yellowish fluid, which is the poison of the viper.

This venomous fluid is secreted by two glands, or rather by two clusters of glands, one on each side of the head, placed on the front of the forehead, directly behind the eye-ball, under the muscle, which serves to depress the upper jaw. Thus, the muscle cannot act without pressing upon them, and promoting the secretion of the fluid, which they are destined to prepare. A little bag, or vesicle, which is connected to the base of the first bone of the upper jaw, as well as to the end of the second, and covers also the roots of the curved fangs, forms a receptacle for the venomous liquor.

The viper is chiefly found in hilly, stony, and woody districts, and it is seldom observed in flat, or marshy places. It is not its nature to attack man, or large animals, except when provoked. Its venom is only employed for the destruction of smaller animals, such as mice, frogs, &c. which are usually swallowed whole, and to the diges-

of which the venomous secretion may

possibly contribute. When, however, a viper is pursued, trod upon, taken hold of, or hurt, it immediately bites, and were it only on account of the shape of the fangs, the wound might be attended with very unpleasant effects; but, it is certain of being so, by reason of the species of inoculation, which complicates it, and of which the mechanism is as follows:

When a viper is about to bite, it opens his mouth very wide. The two curved fangs, which had previously lain flat down, in the cavity of the membrane attached to their base, now project, and become perpendicular to the lower jaw. When the bite takes place, the poison is propelled through the fangs, by the contraction of the muscles, and the closure of the mouth, and it is injected into the wound with a force proportioned to its accidental quantity at the time, and the vigour of the animal.

The bite of a viper is quickly followed by severe effects, some of which are local, and the others general; but, it is with the former, that the disorder invariably commences. At the instant of the bite, the patient suffers in the bitten part an acute pain, which rapidly shoots over the whole limb, and even affects the viscera, and internal organs. Soon afterwards, the wounded part swells and reddens. Sometimes, the tumefaction is confined to the circumference of the injury; but, most frequently, it spreads extensively, quickly affecting every part of the limb, and even the trunk itself. A sanious fluid is often discharged from the wound, around which phlyctenæ arise, similar to those of a burn. After a short time, however, the pain abates considerably; the inflammatory tension changes into a doughy, or œdematous softness; the part grows cold; and the skin exhibits large livid spots, like those of gangrene. The general symptoms also come on with celerity: the patient is troubled with anxiety, prostration of strength, difficulty of breathing, and cold profuse sweats. Vomiting frequently occurs, and sometimes copious bilious evacuations from the bowels. These symptoms are almost constantly attended with an universal yellowness, and excruciating pain about the navel.

These effects occur in the same way in nearly all subjects, with some differences depending upon the particular irritability and constitution of the patient; the high, or low temperature of the atmosphere; the greater, or lesser anger of the viper; the number of its bites; the size of the reptile itself; the depth, to which the fangs have penetrated; and whether the bitten part happens to be one of great sensibility, or was naked, or not, at the time of the accident. In general, weak, pusillanimous persons, of bad constitutions, and loaded stomachs, suffer more sudden and alarming ill consequences, than strong, healthy sub-

jects, who view the danger without fear. Several bites are of course more dangerous, than a single one; and, lastly, it has been remarked, that the venom of the viper is more active in summer, than the spring.

Severe, however, as the effects of the bite of a viper may be, they are far from being so perilous, as they are commonly supposed to be. The injury scarcely ever proves fatal.

The Abbé Fontana has particularly considered this subject, of the bites of serpents, and he agrees with Dr. Mead, that the poison of the viper is neither acid nor alkaline; but, he denies that he could perceive in it any thing like salts, by means of a microscope, which Dr. Mead says he saw. He even denies, that it has any determinate taste when put upon the tongue; though Dr. Mead assures us, that both he and others, who had tasted it, felt it exceedingly sharp and burning to the taste; and he particularly takes notice, that one gentleman, who could not be satisfied without tasting a large drop undiluted with water, had an inflammation of his tongue, and the inside of his lips, of some continuance.

From a vast number of experiments Fontana concludes, that the bite of an ordinary viper will not prove fatal to a full-grown person, nor even to a large dog, though it certainly will do so to smaller animals. Five bites from three strong and healthy vipers were not able to kill a dog weighing sixty pounds; and, as this dog was little more than a third part of the weight of an ordinary man, he concludes, that a single bite can never be fatal to an adult. In confirmation of this, he says, that he has seen a dozen cases himself, and that he has heard of fifty more, only two of whom died. Concerning one of these cases he could get no information; the other perished of a gangrene, twenty days after the bite, and which began in three days after it, the bitten place having been deeply scarified almost immediately after the injury was received. Fontana believes, that much of the faintness, &c. which ensue upon the bite of a viper, are the mere effects of terror. "Upon a person's being bit, (says he) the fear of its proving fatal terrifies himself and the whole family. From the persuasion of the disease being mortal, and that not a moment is to be lost, they apply violent, or hurtful remedies. The fear increases the complaint. I have known a person, that was imperceptibly bit, in the hands or feet, and who, after seeing the blood, and observing a viper near him, suddenly fainted away; one, in particular, continued in a swoon for upwards of an hour, until he was accidentally observed, and recovered out of it, by being suddenly drenched in cold water. We

know, that death itself may be brought on by very violent affections of the mind, without any internal disease. Why may not people, that are bit, die from a disease, produced entirely from fear, and who would not otherwise have died from any complaint produced by the venom?" Although it must be owned, that Fontana bestowed a great deal of attention upon this subject, the above reasoning is hypothetical and inconclusive. Some very timid, delicate, or nervous people might die from fear alone; but, it is by no means fair to conclude, that the generality of people would do so. It is easy to see, that the bite of a viper must be more or less dangerous, according to circumstances.

I have already observed, that the danger of the bite of a viper has been much exaggerated, and that the injury seldom proves fatal. Whenever the patient dies, the catastrophe is always ascribable to the quantity of venom inserted into the wound; the number of bites; their situation near important organs, and the neglect of proper means of relief. In ordinary cases of a single bite upon the extremities, the patients would get well even without any assistance; but, the symptoms would probably be more severe, and the cure slower.

Numerous remedies for the bites of vipers have obtained celebrity. According to certain writers, each of these remedies has effected wonderful cures; and, yet, as Boyer well remarks, every one of them has been in its turn relinquished for another, the sole recommendation of which has frequently consisted in its novelty. Any of these boasted medicines, though of opposite qualities, cured, or at least seemed to cure the patients, and the partisans of each considered, that he had a right to extol his own remedy as a specific, when the patient, to whom he administered it, was seen to recover perfectly, after suffering a train of severe symptoms. But, the reason of this pretended efficacy becomes obvious, when one knows, that the bite of a viper is of itself very rarely mortal to the human subject, and that the severity of the symptoms always depend upon the quantity of the venom in the wound. (*Boyer, Traité des Maladies Chir. T. 1, p. 428.*)

The treatment of the bite of a viper is divided into local, and general means.

The local treatment has for its principal object the destruction of the venom; the prevention of its entrance into the absorbent vessels, or the removal of it from the wound.

Of scarifying the wound, I shall only say, that, it promises no utility, if it be practised with a view of letting such dressings get into the part as are extolled, as specifics; for, we now know, that there is no local application, which is entitled to

this character. Fontana was an advocate for applying a ligature round the limb, in order to check the ingress of the venom into the circulation; he thought he had seen much good result from this practice. No moderns, however, have any reliance upon the method, which is even attended with a risk of causing gangrenous mischief. Suction of the wound has been proposed. It seems founded on reason; but, experience, I believe, has determined little in its favour. It is doubtful, also, whether the venom would not occasion troublesome effects in the person who sucks. At least, Fontana and Mead are at variance upon this point. A cupping glass might indeed be employed without this objection; but, it is probable, that no mode of suction could effectually extract the poison, and the proposal is at present never adopted.

The most certain method of removing the virus consists in the excision of the bitten part. This operation, however, would hardly be proper, unless done immediately after the injury, before much inflammation had come on. It is likewise a thing, to which many patients would not assent, and even some surgeons may deem the proceeding too severe. The particular situation of the bite might also be a strong objection to the practice.

Another plan, which is more commonly preferred, is that of destroying the envenomed part with caustic, or the actual cautery. When this is done in time, the poison is prevented from extending its irritation over the nervous system, through the medium of which all the worst symptoms are usually excited. The caustic, and cautery, may also have the effect of chemically destroying the venom itself, while they must tend to hinder its absorption, inasmuch as they destroy the neighbouring absorbent vessels. Fontana preferred pure potassa, as a caustic. He was convinced by a great many experiments, that it ought to be regarded as a true specific. But, as Professor Boyer sensibly remarks, every caustic must infallibly have the same effect, as its mode of operating is that of destroying the point of irritation, viz. the seat of the venom. In France, liquid caustics are at present preferred; such as the fluid muriate of antimony; or the sulphuric, or nitric acid; because their action is quicker, and they more certainly penetrate to the bottom of the wound. (*Traité des Mal. Chir. T. 1, p. 429.*) Either of these liquids may be applied by means of a slender pointed bit of wood, which is to be dipped in it, and then introduced into the punctures made by the fangs of the reptile. The piece of wood should be withdrawn, wet once more, and applied again. If a drop of the caustic can be inserted, so much the better. When the bite is very narrow and deep, the

caustic cannot well be introduced, before the mouth of the wound is somewhat enlarged with a lancet. A little bit of lint may then be wet in one of the above fluids, and be pressed deeply into the wound.

After the caustic has produced an eschar of the wound, the best application is an emollient poultice.

It is not, however, every bite of a viper, that requires local treatment, even of this degree of severity. As Boyer observes, when the wound is superficial; the viper benumbed with cold; its poison considerably exhausted by its having previously bitten other animals; the swelling inconsiderable; and the patient neither affected with prostration of strength, nor pain about the præcordia; a few drops of ammonia may be introduced into the wound, and a small compress wet with the same fluid applied. Olive oil obtained in England great repute, as a dressing for the bites of snakes, and Pouteau in France afterwards extolled its virtues; but, says Boyer, it possesses no specific efficacy in these cases, as the experiments of Hunaud and Geoffroi have decidedly proved. (*Traité des Maladies Chir. T. 1, p. 431.*)

With respect to the general treatment, if we exclude emetics, of which Dr. Mead had a high opinion, when the patient was much jaundiced, experience decides chiefly in favour of exhibiting stimulating cordials, ammonia, and, particularly, arsenic. The ancients employed theriaca, Mithridates, viper's salt, and the carbonate of ammonia, which means generally answered. Of all stimulants, the aqua ammoniæ puræ is now that, which obtains the greatest confidence; or, else, the *eau de luce*, which only differs from the fluid ammonia, in containing a small quantity of the oleum succinatum. In France, this remedy is at the present time regarded, as having the best claim to the title of a specific for the bite of the viper. (*Boyer, Op. cit.*)

In France, Bernard de Jussieu first tried ammonia in the year 1747 (*See Hist. de l'Acad. des Sciences, 1747*); since which time it has been extensively employed for the cure of the bites of vipers, both as an internal and external remedy. It had, however, been highly praised by Dr. Mead, at a much earlier period. Diluted with oil, says Boyer, it forms a good resolvent liniment. A few drops of it undiluted, when instilled into the wound, make an eligible mild caustic; a compress of lint, wet with it, is a good application to the wound; and, when the medicine is internally taken, it supports the strength, promotes the secretions, and induces copious perspiration.

A few drops of the remedy are to be exhibited every two hours; but, as it is very powerful, it must always be taken in a sufficient quantity of tea, or other drink. The

dose, however, must depend upon the age and constitution of the patient, and the intensity of the symptoms. Four or five drops suffice for a person of weak, delicate, irritable habit; but twelve or fifteen may be given to stronger subjects, and when the symptoms are violent. With ammonia, some practitioners order wine; but, in the early stage of the case, the rest of the treatment is conducted on antiphlogistic principles.

The medicines recommended for the bites of vipers are, according to M. Fontana, not only of very different, but even opposite, qualities. "In no country, (says he) through which I passed, could I ever find any two people or persons, bit by the viper, either in the mountains or valleys, that used the same remedies. Some used theriaca alone, either externally or internally applied; others common oil; a third set used stimulants, such as the strongest spirituous liquors; whilst others, on the contrary, tried every different kind of sedative. In short, there is hardly any active kind of medicine that has not been tried as a cure in this disease: while, at the same time, it is certain, that, under all the varieties of application, none of them died." Hence, Fontana concluded, that none of the remedies made use of had any effect in curing the disease.

Mr. Chevalier was induced to recommend the trial of arsenic in these cases from the facts recorded in Dr. Russell's History of Indian Serpents, on the authorities of Mr. Duffin and Mr. Ramsay, and from which it appears, that the Tanjore pill, of which arsenic is in all probability the chief ingredient, is exhibited with considerable success in India after the bites of venomous serpents.

Mr. Ireland, surgeon to the fourth battalion of the sixtieth regiment of foot, had formerly heard Mr. Chevalier recommend the trial of arsenic for the bites of serpents, and he was resolved to make the experiment whenever an opportunity offered. On his arrival in the island of St. Lucia, he was informed, that an officer and several men, belonging to the sixty-eighth regiment, had died from the bites of serpents, supposed to be the *coluber carinatus* of Linnæus. Mr. Ireland also learnt, that every thing had been tried by the attending medical men to no purpose, as all the patients had died, some in six, and others in about twelve hours, from the time of their receiving the wound.

A case, however, soon came under Mr. Ireland's own observation, and, as nothing, that had been done before, seemed to have been of any service, he was determined on giving arsenic a full trial.

"Jacob Course, a soldier in the York light infantry volunteers, was bitten in the

left hand, and the middle finger was so much lacerated, that I found it necessary to amputate it immediately at the joint with the metacarpal bone.

"I first saw him about ten minutes after he had received the wound, and found him in a torpid senseless state: the hand, arm, and breast of the same side were much swelled, mottled, and of a dark purple, and livid colour. He was vomiting, and appeared as if much intoxicated. Pulse quick and hard: he felt little or no pain during the operation.

"The wound being dressed, and the patient put to bed, I ordered a cathartic clyster, and the following medicine to be taken immediately. *R. Liquor. Arsenic. ʒij. Tinct. Opii gt. x. Aq. Menth. Pip. ʒiss*; which was added to half an ounce of lime juice, and as it produced a slight effervescence, it was given in that state: this remained on his stomach, and was repeated every half hour for four successive hours. In the mean time, the parts were frequently fomented with common fomentation, and rubbed with a liniment composed of *Ol. Terebinth. ʒss. Liquor. Ammon. ʒss. and Ol. Oliv. ʒiss*. The cathartic clyster was repeated twice, when the patient began to be purged; and the arsenical medicine was now discontinued. He had become more sensible when touched, and, from that time, he gradually recovered his faculties; he took some nourishment, and had several hours sleep.

"The next day, he appeared very weak, and fatigued; the fomentation and liniment were repeated. The swelling diminished gradually; the natural colour and feeling returned, and, by proper dressings to the wound and the attention to the state of his bowels, he soon recovered and returned to his duty."

Mr. Ireland recites about four other examples, in which arsenic was exhibited with similar success.

It deserves particular notice, that the liquor arsenici employed by Mr. Ireland was prepared according to Dr. Fowler's prescription, which directs sixty-four grains of arsenic, and as many of the fixed vegetable alkali, to be dissolved in a sand heat, and the solution to be made an exact pint, so that two drachms contain one grain of arsenic in solution. (See *Medico-Chirurgical Transactions*, Vol. 2, p. 393, &c.)

WOUNDS OF THE THORAX.

The term, *thorax*, is said to be derived from the Greek verb, *ῥαπτω*, to leap, because the heart leaps, or pulsates in it.

In the language of anatomy, the thorax or chest implies the upper part of the trunk, or that portion of the body, which is surrounded by the sternum, the ribs, and the dorsal vertebræ.

The chest is subject to different kinds of injuries, produced by external causes, and the important nature of the organs, which it contains, renders the consideration of such cases of the highest consequence to the practitioner. In speaking of *Fractures of the Ribs, Emphysema, Paracentesis of the Thorax, &c.* an account has already been offered, of some affections of the thorax, which are very essential to be known by every surgeon. In the present article, we intend to treat of the subject of wounds, interesting this part of the body; but, before beginning what we have to say, concerning these cases, it seems proper to remind the reader of some anatomical circumstances, relative to the thoracic viscera.

The thorax is a very large cavity, of an irregularly oval figure, bounded in front by the sternum, laterally by the ribs, posteriorly by the vertebræ of the back, above by the clavicles, and below by the diaphragm, a very powerful muscle, which forms a kind of partition between the cavity of the thorax, and that of the abdomen.

The diaphragm is not stretched across, in a straight direction, from one side of the chest to the other; but, on the contrary, descends much further in some places, than in others. If the cavity of the thorax be opened, by a transverse section, about the middle of the sternum, the diaphragm appears, on examination, to be very prominent and convex towards its centre, while it sinks downward at its edges, towards all the points, to which the muscle is attached. At its anterior, and most elevated part, it is fixed to the ensiform cartilage, whence, descending obliquely to the right and left, it is inserted, on both sides, into the seventh rib, all the lower ribs, and, lastly, to the lower dorsal vertebræ. According to this description, it is obvious, that the cavity of the thorax has much greater depth and capacity behind, than before; a circumstance, which surgeons ought to be well aware of, or else they will be liable to give most erroneous opinions, concerning wounds of the chest. For instance, a practitioner, deficient in anatomical knowledge, might imagine, that a weapon pushed from above downward, into the front of the chest, could never reach the lungs, after having penetrated the cavity of the abdomen. It is a fact, however, that no instrument could pass in this direction, even some inches below the highest part of the abdomen, without entering into the cavity of the chest.

The whole cavity of the thorax is lined with a membrane, named the pleura, which is every where adherent to the bones, which form the parietes of this cavity, and to the diaphragm. Each side of the thorax has a distinct pleura. The two membranes

meet in the middle of the chest, and extend from the sternum to the vertebræ. In this manner, two cavities are formed, which have no sort of communication with each other. The way, in which the two pleuræ touch, and lie against each other, forms a middle partition, which is called the mediastinum. These two membranes are intimately adherent to each other, in front, the whole length of the sternum; but, behind, where they approach the vertebræ, they separate from each other, so as to leave room for the passage of the aorta, œsophagus, &c. The heart, enclosed in its pericardium, occupies a considerable space on the left of the mediastinum, all the rest of the cavity of the chest being filled with the lungs, except behind, where the large blood-vessels, nerves, thoracic duct, and œsophagus, are situated. In the perfectly healthy state, the lungs do not adhere to the pleura; but, in this climate, at least, the majority of subjects, who are examined after death, are found to have such adhesions in different places. The disease may probably be occasioned by a very slight inflammation in the chest; and, as the surface of the lungs is naturally destined to be always in close contact with the pleura, and patients are frequently not suspected to have any thing wrong in the thorax, this morbid change being often accidentally discovered after death, in looking for something else; we may conclude, that it does not occasion any inconveniences.

The thorax is subject to all kinds of wounds; but, the importance of these injuries most particularly depends on the depth, to which they extend. Such as do not reach beyond the integuments, do not differ from common wounds, and, when properly treated, are seldom followed by any bad consequences. On the contrary, those which penetrate the cavity of the pleura, even by the slightest opening, are apt to occasion, under certain circumstances, the most alarming symptoms. Lastly, such wounds, as injure any of the thoracic viscera, are always to be considered, as placing the patient in a state of considerable danger.

From what has been said, it appears, that wounds of the thorax are very properly divisible into three kinds: viz. 1. such as only affect the skin, and muscles; 2. such as enter the cavity of the chest, but injure none of the viscera; 3. others, which injure the lungs, or some other viscus.

SUPERFICIAL WOUNDS OF THE THORAX.

Immediately a surgeon is called to a recent wound of the chest, his first care should be to endeavour to ascertain,

whether the weapon has penetrated the chest, or not. An opinion may be formed on this subject, by attending to several circumstances. 1. Surgical writers recommend, for this purpose, placing the wounded person in the same posture, in which he was, when he received the wound, and then carefully examining with a finger, or probe, the direction, and depth of the wound. 2. We are also advised, if possible, to get the weapon, with which the injury was inflicted, and, by the bloody part, judge how far it has penetrated. 3. We are advised to inject some liquid into the orifice of the wound, and to observe, whether it regurgitates immediately, or lodges in the part. 4. The colour and quantity of the blood, emitted from the wound, are to be noticed, and whether any is coughed up. 5. We are to examine, whether the circumference of the wound becomes emphysematous, or any air escapes from its orifice in respiration. 6. Lastly, the state of the pulse and breathing is to be attended to.

In treating of wounds of the abdomen, I have cautioned surgeons against being too officious in probing such injuries, merely, for the sake of gratifying their own curiosity. The same advice is equally applicable to the present cases. Surgical authors have, perhaps, dwelt too much on the subject of probing wounds of the abdomen, and thorax, and their readers imbibe an opinion, that, until they have traced the wound, with their finger, or probe, to its very bottom, and termination, they are not qualified to put in practice any surgical measures. The only advantage of knowing, that a wound penetrates the chest, is that the practitioner immediately feels himself justified in having recourse to bleeding and other antiphlogistic means, and thus averts inflammation of the pleura, and lungs, which affection, when it has made progress, often proves fatal. However, there can be little doubt, that if the nature and depth of the wound cannot be readily detected, with the eye, the finger, or a probe, it is much safer to bleed the patient, than to put him to useless pain, irritate the injury with the introduction of instruments, and waste opportunities of doing good, which too frequently can never be recalled. In short, it is better, and more advantageous, for all patients, that some of them should lose blood, perhaps, unnecessarily, than that any of them should die, in consequence of the evacuation being omitted, or delayed.

Almost all the writers, who have taken pains in directing, how wounds of the thorax should be probed, conclude with remarking, that, however advantageous a knowledge of the direction and depth of the wound may be, much harm has fre-

quently been done by pushing the attempts to gain such information too far. It is, perhaps, of greater importance to ascertain, by some kind of examination, the extent of a wound, which does not reach beyond the integuments, or intercostals, than to know, whether the wound extends into the cavity of the chest. For, even when the pleura is found to be divided, if the wound is attended with no urgent symptoms, the information is of no practical use, if we make it a rule to adopt, without the least delay, a strict antiphlogistic plan of treatment, in all cases, in which there is any doubt, or chance of the parts, within the chest, being wounded, and likely to inflame. Besides, very frequently, the symptoms are more urgent and alarming, than they could be, were only parts on the outside of the thorax injured; and, in these instances, it is obvious, that the employment of a probe cannot be necessary for discovering, that the wound extends into the chest.

We have above adverted to inspecting the weapon, with which the wound was inflicted, as a mode of gaining some information, concerning the probable depth of the wound. Enquiry may also be made, in what direction it was pushed; and, sometimes, the blood on the instrument will denote how deeply it penetrated. It is clear, however, that though information of this kind may be obtained, in a few instances, in general, it is otherwise.

When, by any of the above means, it cannot be learnt, whether the wound penetrates the chest, or not, various authors recommend the injection of luke-warm water. If the water regurgitates at once, they conclude, that the injury is only superficial; but, when the fluid, either wholly, or in part, continues in the wound, without producing any external swelling, they infer with certainty, that an opening has been made in the pleura. This plan of examining the state of parts, however, is much more objectionable, than the employment of a probe; for, if the liquid be propelled, with a certain degree of force, for the purpose of driving it to the bottom of the wound, parts, which were not before hurt, will in this manner become injured. The fluid may also be injected into the cavities of the cellular substance, and may seem to be passing through the track of the wound into the chest, while, in reality, not a drop does so. Besides, is it a warrantable proceeding to try to insinuate any quantity, or kind, of liquid, whatever, between the pleura and lungs, into a situation, in which it must necessarily obstruct the important function of respiration, and cause serious inconvenience?

When air issues from the wound in ex-

piration, there is ground for suspecting, that the lungs are wounded. But, authors have erred in setting down this circumstance, as an infallible criterion of the nature of the accident; for the same symptom may happen, when there is only an opening made into the chest, without any injury of the lungs whatever. The air, which is expelled in expiration, has previously got into the bag of the pleura through the wound, in inspiration. In such cases, the external air insinuates itself, through the opening into the chest, between the pleura and lungs, and, it will be seen to escape, during expiration, although the lungs may not be at all wounded. In order to remove all doubt upon this subject, the patient should be requested to expire, as strongly as he can, so as to force out whatever air may have accumulated in the chest. At the end of each expiration of this kind, care must be taken to bring the skin closely over the orifice of the wound, and to keep it thus applied, during each following inspiration, for the purpose of preventing the external air from entering. In this way, if there be no wound of the lung, all the air will soon be expelled; but when some still continues to come out in expiration, we may conclude, with certainty, that the lungs are wounded.

Sometimes, an emphysematous swelling takes place round wounds of the thorax, in consequence of a quantity of air diffusing itself in the cellular substance. This symptom is very uncommon in wounds, which are straight, and ample; but, it is by no means, unfrequent, in wounds caused by narrow stabs, more especially oblique ones, and by the points of broken ribs. (See *Emphysema*.) When a considerable quantity of blood flows from a wound of the chest, there is great cause for conjecturing, not only, that it has penetrated the cavity of the thorax, but, also, that some of the thoracic viscera are injured. Excepting the intercostal arteries, which run along the lower edges of the ribs, and the trunks of the thoracic arteries, all the other vessels, on the outside of the chest, are very inconsiderable. A proper compression will soon shew, whether the blood escapes from an artery on the outside of the cavity of the pleura. The situation, and direction of wounds very frequently denote at once, that the hemorrhage cannot proceed from any of the trunks of the thoracic arteries.

Even the appearance of the blood, which comes from the wound, may lead to some conjectures, concerning the depth of the injury. The blood, which flows from wounds of the lungs, is of a brighter scarlet colour, and more frothy, than that which is emitted from the vessels of any other part.

There can be no doubt of the lungs being wounded, when the patient is observed to spit up blood; but the absence of this symptom is, by no means, to be regarded as a proof of the contrary.

The state of the pulse, and that of respiration, ought to be particularly attended to by the practitioner. Neither one, nor the other, seems altered, at least at first, when wounds do not reach more deeply, than the integuments; but, those, which penetrate the cavity of the thorax, and, especially, such as injure any of the viscera, may frequently be distinguished, from the very first moment of their occurrence, by their effects on the sanguiferous system, and the function of respiration. When the lungs happen to be wounded, at a place where they have contracted an adhesion to the pleura, the wound may extend to a great depth, and yet no air may be diffused in the cavity of the thorax, nor the functions of these organs be at all disturbed. But, when either air or blood, has insinuated itself between the lungs and the pleura, the lungs become immediately oppressed, the breathing is attended with difficulty, the pulse is weak, contracted, and intermittent; and no doubt can be entertained, concerning the nature of the injury.

Having said enough, relative to the diagnosis of wounds of the thorax, we shall next consider their treatment.

Wounds of the thorax, which only injure the integuments, are not generally attended with any danger; they heal with the same readiness, and by the same means, as common, superficial wounds in any other part of the body.

But, when the surgeon has to treat a punctured, or a gun-shot wound, it is too frequently directed, by writers on surgery, to lay open the track of the injury, from one end to the other with a knife, if its course should not be too extensive, and then to dress the cavity down to the bottom. Such authors also add, that when the track of the wound is so extensive, as not to admit of this plan, it is better to introduce a seton through it. Their object, in employing these methods, is to prevent the outer part of the wound from healing too soon, and thus give time for the whole of it to heal in an equal degree. Afterwards, they advise the silk of the seton to be gradually diminished, and, when, at length, the whole of it is removed, a slight degree of compression, kept up for a few days, is deemed sufficient for the completion of the cure.

The French surgeons have the discredit of bringing setons into fashion in this branch of surgery, and I am particularly glad, that an able modern writer has exposed the absurdity of the practice. "We find (says Mr. John Bell) the history of

it, to be plainly this: that as Guy de Chauliac, Paré, and all the older surgeons, did not know how to dilate gunshot wounds, they found these same setons useful in bringing the eschar sooner away, and in preserving an open wound; and, as they believed the wounds to be poisoned, they took the opportunity of conducting, by these setons, whatever acrid medicines might, according to the prevailing doctrines of that time, have any chance of correcting the poison." Mr. J. Bell notices, how surprising it is to see the cruelty, and perseverance, with which some modern practitioners, particularly, French, draw these cords through wounded limbs; and when the roughness of such a cord, or the acrimony of the drugs conveyed by it, produces a copious suppuration, these men are delighted with such proofs of their success. The setons have been introduced by the French surgeons, across the thickest parts of the limbs, along the whole length of the forearm, and, at the same time, frequently through the wrist-joint. The setons have also been covered with stimulating applications. Profuse suppurations, and dreadful swellings of course ensued; still, as Mr. J. Bell has remarked, these cruelties were continued, till the wound healed almost in spite of the pain; or till the coming on of very dreadful pain, great suppurations, convulsions, &c. made the surgeon discontinue the method, or even amputate the limb. The French have become so familiarized to setons, that they do not restrict their use to flesh wounds, they pass them quite across the thorax, across the abdomen, and even through wounds of the knee-joint.

When we wish to excite inflammation, in the cavity of the tunica vaginalis, for the purpose of radically curing a hydrocele, we either pass a seton through the part; lay it open with an extensive incision; cram a tent into it; or inject some irritating fluid into it. While the animal machine continues the same, says Mr. John Bell, the same stimuli will produce the same effects, and a seton, injection, or long tent, if they produce pain and inflammation in the scrotum, will not be easy in the chest; and, unless we can use them in the chest, with the same intentions, with which we use them in the hydrocele, (in other words) unless we are justified in inflaming the chest, and causing an adhesion of all the parts, we cannot use them, with any consistency, or good sense.

With regard to the cases, which the French adduce in confirmation of the good effects of their plans, I am entirely of opinion with Mr. J. Bell, that the facts only prove, that the patients recovered in spite of the setons. "It is like (adds this

author) what happened to a surgeon, who was dabbling in the thorax with a piece of caustic, which fell directly into the cavity of the chest, where it caused very large suppurations, and yet the patient was saved. The patient recovered, in spite of the caustic, just as M. Guérin's patient, and many other poor unhappy souls, who lived in spite of the setons. One would think, that people took a pleasure in passing setons across the eye-ball, the chest, the knee-joint, &c. merely to make fools stare, when the business might be as effectually done with an abscess lancet."

Mr. John Bell, in his usual lively style, makes the employment of tents, in wounds of the chest, seem equally ridiculous and improper. Indeed, he says, *he knows of no occasion in all surgery, in which tents can be useful, except in the single one of a narrow opening, which we desire to dilate, in order to get at the bottom of the wound; and where either, on account of some great artery, or the fearful temper of our patient, we dare not use the knife.* (See J. Bell on Wounds, Discourse 2, Vol. 2.)

Having hitherto been engaged, rather in pointing out, what ought not to be done, that what ought, I shall next make some remarks on the line of conduct, which should be adopted, in cases of wounds of the parietes of the chest.

When the wound is a common cut, the sides of the division are to be brought into contact, and maintained in this position, by the aid of strips of adhesive plaster, compresses, and a bandage, until they have grown together. There will very seldom be any occasion to employ sutures in these instances, if the surgeon only observe to relax such muscles as happen to be cut, or to be situated immediately under the wound of the integuments.

As cut wounds seldom, or never penetrate the chest, and there is generally no reason, why they should not unite by the first intention, without being followed by extensive inflammation and abscesses, only a moderate use of antiphlogistic means will usually be necessary. Bleeding will not often be requisite. The grand objects are, to keep the patient in a quiet state, on rather a low diet, and to hinder him from taking wine, porter, spirits, or any stimulating beverages.

If the wound, instead of healing favourably, should inflame, the treatment should be regulated by the principles laid down in the article *Inflammation*. If it should suppurate over its whole surface, still the sides generally ought to be kept approximated by one, or two strips of sticking plaster; for, in this way, the cavity, which must now be filled up by granulations, will be rendered much smaller,

than it otherwise would be. The softest particles of lint may be laid in the cavity of the wound, which the sticking plaster does not entirely remove, and over the whole a pledget of some mild, unirritating ointment. No pressure is now proper, until the inflammation diminishes; and if the matter should be very copious, attended with much surrounding inflammation, the best application would then be an emollient poultice. The patient should also be bled, and leeches may be applied, as often as necessary, round the wounded part.

When the case is a stab, or punctured wound, the fibres of the divided parts are not simply cut, they are also considerably stretched, bruised, and otherwise injured. Hence, they cannot, in general, be expected to admit so readily of being united, as the sides of a clean incision, made with a sharp instrument. However, the possibility of uniting the opposite sides of punctured wounds must depend very much on the shape of the weapon, and the suddenness, roughness, and violence, with which it was driven into the part. A prick with a needle is a punctured wound; so is that so often made by surgeons with their lancets; yet, these injuries do not frequently bring on violent inflammation, and abscesses, like those wounds often do, which are inflicted with bayonets, and pikes.

Let us suppose a man to have received a thrust of a bayonet, which has run into the skin and muscles, covering one side of the thorax; what plan can the surgeon follow, with the greatest advantage to his patient?

Instead of laying open the whole track of such a wound with a knife, as is barbarously recommended in many of the principal works on surgery; instead of drawing a seton through its whole course, or of cramming into the part, a hard, irritating tent; the practitioner should take whatever chance there is of uniting the wound without suppuration. For this purpose, he should recollect, that the great degree of violence, done to the parts in punctured wounds, is the reason, why they are so apt to inflame and suppurate. Hence, the expected inflammation is (to use a vulgar expression) to be knocked on the head, if possible, in the very first instance; and immediately the wound is dressed, the patient should be freely bled, and take some saline purgative medicines. With regard to the dressings, the orifice of the wound may be closed with sticking plaster, if the circumstance is practicable; if not, it may be covered with any mild superficial applications. Over and around these, the surgeon may lay some folds of linen, which are to be kept continually wet with cold water, or a lotion containing the acetite of lead. Many patients, however, have a strong dislike to the application of cold

fluids to wounds situated upon their trunk, and, although in principle such applications are right, it is often necessary to dispense with them in practice. A roller is to be employed for retaining the dressings; but, it need not be put on tight, as pressure is more likely to do harm, than good. Thus the inflammation of the wound will be moderated; the extravasation of blood prevented; the chance of union by the first intention taken; and all painful operations avoided.

If strict antiphlogistic means be employed, many stabs unite without abscesses, when surgeons entertain little hope of such success.

But supposing, that suppuration follows, and a collection of matter takes place, will the patient suffer more, or be put into greater danger, by having a proper depending opening, of just sufficient size, now made into the abscess in an eligible place, than if he had submitted to have the formidable operation of laying open the whole extent of a stab, performed in the first instance. In short, will he suffer half so much, be half so long in getting well, or have to encounter half the danger? With all this advantage, he will have taken a certain chance, which attends all these cases, of the wound becoming united by, what is called, the first intention, that is to say, without any suppuration. I need not enlarge upon this subject, but refer the reader to what has been said on *Punctured Wounds* in this article, and to the treatment of abscesses, in the article *Suppuration*. Gun-shot wounds, only injuring the parietes of the chest, are to be treated, according to the principles explained in the article *Gun-shot Wounds*.

OF WOUNDS PENETRATING THE CAVITY OF THE THORAX.

Wounds, which penetrate the chest, are always dangerous, and, consequently, claim the utmost attention of the practitioner. We shall first treat of such wounds as enter the cavity of the thorax, but without injuring any of the viscera.

In the healthy state, the lungs so completely fill the cavity of the thorax, that, both in inspiration and expiration, they are always in close contact with the pleura; and, whenever air, blood, or any other matter, insinuates itself between the outer surface of the lungs, and the inner one of the pleura, more or less oppression, and difficulty, of breathing immediately take place. In all wounds, attended with a division of the pleura, occurring in a situation, where there happens to be no adhesion between this membrane and the lungs, some of the external air, or a small quantity of blood, or both, can hardly fail to get into the cavity of the thorax. If one of the in-

tercostal arteries should be wounded, and the external wound be, at the same time, very narrow, the blood, furnished by this vessel, may insinuate itself inwardly into the chest, and immediately occasion oppression of the breathing, and other symptoms of pressure on the lungs. Of what is to be done in this case, we shall presently speak.

When a wound is known to have entered the pleura, and there is no symptom leading to a suspicion, that the lungs, or any large vessel, is wounded, the injury is to be dressed according to common principles, and the more superficially the better. Authors also usually direct us, just before we close the opening, to tell the patient to make a deep inspiration, for the purpose of expelling as much of the air as possible, which may have got into the cavity of the pleura. At the end of such inspiration, the edges of the wound in the skin are to be brought together, and kept so, with sticking plaster compresses, and a roller, applied round the body. The other grand indications, in the treatment, are to avert inflammation of the pleura and lungs, by a rigorous adoption of the antiphlogistic plan, copious bleeding, in particular, not being forgotten.

Let us now consider such wounds as penetrate the chest, and are complicated with some of the following circumstances:

1. With the presence of foreign bodies.
2. With injury of one of the intercostal arteries.
3. With a protrusion of a portion of the lungs.
4. With a considerable emphysema.
5. With an extravasation of blood in the thorax.

1. Almost all wounds, which penetrate the chest, occasion pain and difficulty of breathing. Many of them are also followed by an emphysematous swelling round the wound; the patient is frequently attacked by a spitting of blood; and, after having had, for some time, a small, contracted, irregular pulse, with a pallid countenance, and cold extremities, he is too often seized with febrile symptoms. These should be counteracted by bleeding, diluent beverages, a proper regimen, quietude, and external applications of the resolvent kind. If such symptoms should continue longer, than the first few days, without any diminution, writers inform us, that there is ground for suspecting, that they depend upon the presence of some foreign body. However, it may be doubted, whether Sabatier's advice, immediately to make search after the extraneous substance, is proper, under these circumstances. For my own part, I cannot think the symptoms, above related, by any means unequivocal, and even were they so, the practice would still be questionable. (See *Médecine Opératoire*, tom. 2. p. 244.)

M. Sabatier has quoted the two follow-

ing cases, for the purpose of shewing what may be attempted in these cases.—“A man, twenty-seven years of age, was struck very violently with a knife, on the outer part of the fourth true rib. Simple dressings were applied for the first few days; but, a considerable coughing, and spitting of blood ensuing, M. Gerard was consulted. This gentleman found, that the symptoms depended, on the presence of a piece of the blade of the knife, which pierced the rib, and projected, to the extent of about six lines, into the cavity of the thorax. So little of the foreign body was on the outside of the rib, and it was so fixed in the bone, that it could neither be extracted with any kind of forceps, nor even moved in the least with a leaden mallet, &c. Although, in these urgent circumstances, there seemed to be no other resource, except that of sawing, or cutting out the portion of the rib, M. Gerard thought, that an attempt might first be made to extract the foreign body, by pushing it from within outward. For this purpose, having put a steel thimble on his index finger, he introduced it into the cavity of the thorax, and thus succeeded in pushing out the piece of the knife.

“The foreign body being taken out, M. Gerard next introduced his finger, without the thimble for the purpose of examining, whether the inner surface of the rib was splintered. A spicula of the bone was in fact detected, capable of pricking the parts within the chest; but, it was too firmly connected with the rest of the rib to admit of being completely taken out. Hence, M. Gerard adopted the plan of making the splintered piece of bone continue in close contact with the main portion, by immediately surrounding the whole rib, at the splintered part, with a ligature. This was passed by means of a curved needle, and firmly tied over a thick compress.” To these ingenious proceedings, as the French term them, was imputed, not only the cessation of all the bad symptoms, but a speedy recovery. (See *M. de la Faye's Notes to the Traité des Opérations de Dionis*.)

M. Sabatier quotes another case, which we next insert in this Dictionary, for the information of the reader.

An officer was shot in the left side of the chest. The ball entered about where the bone and cartilage of the seventh true rib unite, and came out in the situation of the angle of the same bone, which was broken in two places. The neighbouring part of the first false rib was also broken behind. Incisions were made, which enabled the surgeon to take away several splinters of bone, and facilitated, (that absurd French practice) the introduction of a seton. Soft mild dressings were put on the wound. In consequence of the dangerous nature of the accident, the patient was bled twenty-

six times, with a view of relieving the fever, difficulty of breathing, and spitting of blood. On the fifth day, suppuration had begun to take place, and the seton could be easily drawn. In about a fortnight, the patient experienced a considerable abatement of his sufferings, and passed some of the ensuing days in a tolerably easy state. Circumstances having made it necessary to move him to another place, on the twenty-fourth day, he had an uneasy night; febrile symptoms took place, and the discharge was not of its usual consistence. Two more bleedings were practised, and the critical state of the patient led the surgeon to examine the wounds again. On passing a finger into the wound, which was situated behind, a foreign body was felt, and easily extracted. It proved to be a piece of the patient's coat. A spicula of bone was also felt more deeply lodged, which required the posterior wound to be dilated for its extraction. Some amendment followed the removal of these extraneous substances.

On the thirtieth day from the receipt of the wound, the bad symptoms having come on again, two more bleedings were practised, and, as fear was entertained that the seton did harm, it was suppressed. The patient now first made complaint of feeling something, which pricked him, in a deep situation, between the two openings of the wound. It was found impracticable to ascertain the cause of this sensation, without dividing all that intervened, between the two wounds, and which formed a space of seven or eight finger-breadths. This serious operation was resolved on in a consultation, and M. Guerin set about it by cutting from within outward, the parts between the two ribs, with the aid of a finger introduced into the posterior wound. Care was taken not to cut near the lower edge of the upper rib. In this way, the whole track of the ball was laid open, and in the middle of it, a very sharp splinter was found, sticking in the substance of the lungs. This was removed, and the wound dressed with simple applications. From this day all the bad symptoms ceased, and the cure was completed at the end of four months. (*Obs. de Guerin in Mem. de l'Acad. de Chirurgie, tom. 2; 4to.*)

Mr. John Bell has taken notice of the preceding case: he observes, that some of M. Guerin's steps were bold and good, as well as successful; but, that the employment of the seton was wrong. The example teaches us several important circumstances: 1. The propriety of making very free dilatations for the extraction of splintered pieces of bone. 2. The utility of repeated copious bleedings, which, in the above case, indeed, had the greatest effect both in preventing such hemorrhage in the chest, as would probably have produced

suffocation, and also in averting a degree of inflammation in the thorax, which would have proved fatal.

Mr. John Bell very judiciously condemns the seton, used by M. Guerin: "Had M. Guerin (says he) been asked what good it was to do, it would have been difficult for him to have invented even a plausible apology for the practice, which if it was not doing good, could not fail to do harm. Was this seton necessary for keeping the wound open? No, surely; for the wound could not have closed, while it was irritated, and kept in suppuration by splinters of bone, and a piece of cloth within the breast. Was it to draw the piece of cloth out? Surely, in the course of twenty days, a piece of cloth would have had some chance, at least, of being floated towards the wound, either by the natural flux of the matter, or by the help of a mild injection. Was it useful in supporting the discharge? This would have been a sore question for M. Guerin; for it supported the suppuration only by inflaming the chest; and where inflammation of the chest, or high cough, or bloody expectoration, or a profuse discharge, were the chief dangers, a great seton could hardly be a comfortable inmate in the breast. I think one might very boldly promise to produce bloody expectoration and terrible cough, profuse suppurations, and oppression, to any degree, by drawing such a cord across a sound thorax."

Mr. John Bell next censures M. Guerin for not having discovered the pricking piece of bone before the thirty-eighth day; and imputes this, in some degree, to the seton, the pain of drawing which across the chest deadened every lesser pain, and, consequently, the patient could not feel the trifling pricking of the bone, till his greater sufferings from the seton were allayed. "In short (says Mr. John Bell) M. Guerin passes a great strap of coarse linen across the cavity of the chest, and when it causes inflammation, he thinks to subdue it by bleeding; when M. Guerin continued for thirty days drawing a coarse seton through the breast every morning, and bleeding for the cough every night, what did he do, but raise inflammation with his left hand, to shew how well he could cure it with his right?" (See *John Bell on Wounds, Vol. 2, p. 36—38.*)

2. When one of the intercostal arteries is wounded in the track of a narrow oblique wound, the nature of the accident cannot at first be known. The blood, which the vessel pours out, commonly makes its way into the cavity of the chest, where it causes an extravasation, which is more, or less considerable. But when the wound is ample, and penetrates in a direct manner, the effused blood, which has all the characters of arterial blood, leaves no doubt, concerning the injury of an intercostal ar-

tery. However, should there still be the least uncertainty, it may easily be dispelled, by introducing the end of a finger into the wound, and making pressure with it on the lower edge of the rib, which corresponds to the vessel suspected to be injured. Some have recommended introducing, under the rib, a hollow cylindrical piece of pasteboard; and they infer, that when the blood flows through its cavity, it comes from the intercostal artery; but, that if it passes out underneath the pasteboard, it issues from the cavity of the thorax. However, besides several objections, which might be urged against this method, its adoption cannot be made, unless there be a large, open wound, in which case, the plan may be dispensed with, because the place whence the blood flows, is now visible.

Surgeons, long ago, began to exercise their industry, in devising some means for suppressing hemorrhage from the intercostal arteries, in wounds of the chest. Gerard first proposed to stop such hemorrhage, by means of a ligature. His plan was to enlarge the external wound, as far as the upper edge of the rib, corresponding to the intercostal artery, which is wounded, and then to introduce into the chest a common curved needle, armed with a ligature, to which is attached a dossil of lint. The needle is to be passed behind the rib, rather higher than the superior edge of the bone. The point of the instrument is then to be pushed, from within outward, and brought out through the external wound, together with the ligature, which follows it. When the dossil has come into contact with the artery, the two ends of the ligature are to be tied over a thick compress, placed on the outside of the rib. In this manner, the bone is surrounded with the ligature, and the artery compressed.

Goulard, a surgeon of Montpellier, having found difficulty in passing a common needle, whose shape little corresponded to the track, through which it had to pass, being curved towards its point, and straight towards the eye, had a particular one constructed for this operation. He also feared, that the former instrument, which has a sharp point, and edges, might wound the lungs. The one, which Goulard invented, formed three-fourths of a circle, and was fixed on a long handle, which facilitated its being introduced. The eye, in which the ligature is to be put, is situated near the point, which is a little blunted, and the ligature lies also in a groove, constructed along the convexity of the instrument. When this needle had passed through the intercostal muscles, and its point had made its appearance over the rib, which was above the artery, the ligature used to be untied, and held, while the needle was with-

drawn at the place, where it had entered. The ligature was then tied, just in the same manner, as in Gerard's method.

Since the use of the ligature, it has been thought, that compression might answer better. Löttery, professor of anatomy in the university of Turin, constructed, for this purpose, a steel plate, which he submitted to the inspection of the Academy of Surgery, and it is described, and engraved in the second volume, 4to. of the *Memoirs of this Society*. This plate, as we have said, is made of steel, and is of a long shape; narrow at one end; broad at the other; curved in two directions at its narrow part; and pierced at this place with some holes, by means of which a compress, calculated for compressing the artery, is fastened on the instrument, an opening having been first made in the situation of the wound of the vessel, for the purpose of giving vent to blood, already extravasated in the chest. The other end of the steel plate has two long parallel slits, through which a ribband is passed, in order to fasten the instrument.

This steel contrivance is used in the following manner: when the wound, corresponding to the intercostal artery, is sufficiently extensive in the transverse direction, the narrow, bent end of the instrument is to be introduced, in such a way, that the lower edge of the rib above may lie in the concavity of the curvature, and the compress press on the edge of the bone, and, of course, on the artery. The rest of the instrument applies itself to the side of the thorax, in which situation it is to be fastened. When the wound is not ample enough, a sufficient dilatation of it must be made for the introduction of the instrument.

M. Quesnay made use of a piece of ivory, which he covered with lint, &c. and then introduced within the chest. The instrument was then drawn from within outward, by means of a ribband, which was fastened to it, and thus the necessary compression was produced.

Quesnay's plan is somewhat like that invented by Löttery. But, to have introduced the compress entirely into the thorax, together with the ivory, which was the basis of it, and then to have drawn the contrivance from within outward, as was probably intended, a very large wound would have been indispensable. This is also one of the objections to Löttery's instrument, which, in fact, could only be employed, when there was a free and ample opening. However, there are other objections to this instrument: it obstructs the motion of the thorax; it prevents blood, extravasated in the chest, from readily making its escape, notwithstanding the opening made in the curved part of the instrument; and, lastly, it does not effectually stop the bleeding;

because it does not hinder the rib from rising, against which the pressure should be made, and, consequently, the hemorrhage may then take place.

Belloque, seeing the inefficacy of all the compressing means, used before his time, and their inconveniencies, invented an instrument, which, he says, is calculated for making proper pressure, and, following the motion of the ribs, without hindering the escape of extravasated blood. The machine is engraved, and described, in 2 tom. 4to. of the *Memoirs of the Royal Academy of Surgery in France*. It is composed of two plates, which are wadded, and capable of being approximated, by means of a screw. This instrument, as M. Sabatier observes, does indeed promise to be completely effectual in its action; but, it is complicated, and awkward, and its utility is founded on the supposition of the wound being larger, than wounds are, which are made with common weapons.

As the object is to make pressure on the artery, it is quite unnecessary to have, for this rare accident, numerous instruments, which could seldom be at hand, and which are also liable to all the above objections. A common dossil of lint (says Sabatier), fastened to a strong ligature, and introduced between the two ribs, or even quite into the chest, and then drawn, from within outward, like Quesnay's compress, would fulfil every desirable purpose. This being done, the external wound should be covered with simple dressings, and a bandage applied round the body. The patient should be freely, and repeatedly bled, and treated on the most rigorous antiphlogistic plan; every method being adopted, which seems proper, in cases of wounds penetrating the chest, which are almost always attended with symptoms of high inflammation and irritation. The dressings should not be removed, till the wound has supplicated, and then the rest of the treatment resembles that, which becomes necessary in wounds with extravasation, of which we shall presently speak.

Professor Assalini very properly joins all the best modern surgeons in reprobating the introduction of the preceding contrivances and extraneous substances into the chest, in order to stop hemorrhage from the intercostal artery. All these methods are calculated to excite a dangerous degree of inflammation in the chest. Hence, he prefers, simply cutting the artery across, so as to allow it to retract, and if this plan fail in stopping the bleeding, he thinks it better to close the wound. Should the blood find its way into the chest, it is true, the consequences will be serious, but not fatal; and if the symptoms require it, the operation of empyema may afterwards be done. A small quantity of effused blood, however, may possibly be absorb-

ed, and no such proceeding be requisite. (See *Assalini's Manuale di Chirurgia*, p. 58—59.)

3. The protrusion of a portion of the lungs, in consequence of wounds penetrating the chest, is a very unusual case; but there are some instances recorded by writers. Schenckius relates an example, taken from Rolandus, one of the commentators on Albucasis. Rolandus having been called to a man, who had been wounded in the thorax, six days before, found a portion of the lungs protruded, and in a state of mortification, in consequence of the compression, which it had sustained. This surgeon extirpated the part, and applied astringent powders to the wound: the patient recovered in a very little time, without any indisposition whatever remaining.

Tulpius has recorded a similar fact. A man received an extensive wound, just below his left nipple. His naturally gay disposition, however, led him to neglect the injury; and on the third day, a piece of the lungs, three finger-breadths long, protruded at the wound. The patient went to Amsterdam, whence he was distant two day's journey, for the purpose of receiving succour in one of the hospitals of that city. The protruded piece of lung, which was already mortifying, was tied, and cut off with scissars. It weighed three ounces. The wound healed in a fortnight, and the patient experienced no complaint afterwards, except a slight cough, which troubled him from time to time. The man survived the accident six years, leading a wandering, drunken life. After death, nothing particular was observed in the thorax, except that the lungs had become adherent to the pleura, in the situation of the wound. Fabricius Hildanus also relates a case, which was communicated to him by Abel Roscius. A man was wounded with a knife, between the fifth and sixth ribs, near the sternum. A piece of lung protruded through the opening, and it was wished to reduce the part; but, as it seemed to assume a livid colour, it was extirpated with the actual cautery. Having dilated the wound, and kept the ribs apart, with a wedge made of wood, the portion of lung, which had been girt by the opening, was returned. The patient after taking what were called, pectoral and vulnerary medicines, soon got well, and felt no complaints in his chest afterwards.

A fourth example of a piece of lung, making a protrusion through a wound in the thorax, is among the cases, recorded by the celebrated Ruysch. The servant of a sea-faring man was wounded in the anterior and inferior part of the chest, and was immediately attended by a surgeon, who mistook the protruded piece of lung, for a portion of omentum, and

applied a tight ligature round it. Ruysch, who was called in to the case, soon detected the error, which had been committed; but, he had no apprehensions, as he was convinced, that the wound would heal very well, as soon as the tied piece of lung was detached. The event justified his prognosis, and the patient recovered.

When the piece of protruded lung is sound, and its small size will admit of its being reduced, the attempt ought to be made, without the least delay. It should be done on the same principles, as those, on which we return into the abdomen a piece of protruded intestine, or omentum. (See *Wounds of the Abdomen*.) A recurrence of the accident is to be prevented by closing the wound, and placing a compress over it. But, when the piece of lung is already in a mortified state, in consequence of the constriction, which it has suffered, or when its large size prevents reduction, Sabatier is of opinion, that the only resource is to extirpate the part, after applying a ligature round its base. If the latter step were not taken, a dangerous hemorrhage might follow, or else an extravasation of blood in the thorax. (*Médecine Opératoire*, tom. 2, p. 224.) However, the practice just now recommended seems very questionable: in the instance of mortification, extirpation is clearly unnecessary, as the dead part will naturally be thrown off by a spontaneous process; and, when the wound is too small to allow the part to be returned, ought it not to be dilated, rather than cut off a considerable portion, or even any, of the lung?

After the battle of Waterloo, I had a patient with a protrusion of a piece of lung four or five inches in length. The part was much bruised, and could not be easily reduced. I therefore applied a ligature round its base, and cut it off. Previously, however, I made an incision into it in order to ascertain whether it would bleed freely, which being the case, induced me to use a ligature. I was afterwards informed by Mr. Collier, staff surgeon, that the man died.

4. Emphysema is another symptom, with which wounds penetrating the chest are frequently complicated, especially, when they are small, and do not enter the thorax in a direct manner. When such wounds are small, and not straight in their course; when their track is rendered impervious either by some change in the situation of the muscles, by the swelling, by clots of blood, or by any extraneous substances; air may insinuate itself into the cellular substance, so as to cause a great deal of tumour and distention. The emphysema is easily distinguishable by the tumefaction of the part affected, without any pain, or change

of colour in the skin, and by the crepitation, which is perceptible, on making the air quit the situation which it occupies, and pass into the adjoining cavities of the cellular substance. The emphysema may take place, in cases in which the lungs are not wounded, and also in others, in which they are so. In the first instance, the emphysematous swelling is caused by the external air, which insinuates itself into the cavity of the thorax through the wound, during the first inspirations, which follow the occurrence of the accident, and the same air is expelled in the subsequent acts of expiration. In the second case, the emphysema arises from the escape of air from the lungs, during inspiration, first into the cavity of the thorax, and thence, through the inner opening of the external wound, into the cellular substance.

I should have deemed it unnecessary to have said any thing in this part of the work, on the present subject, and have contented myself with referring to the article *Emphysema*, were not the cause of this symptom rather perplexing, and, did I not hope, that the following extract from Dr. Halliday's publication will tend to facilitate the comprehension of these cases. This gentleman mentions the following circumstances, under which air may escape from the lungs, or emphysema arise.

1st. "An injury or disease of the pleura pulmonalis, causing a wound or ulceration of that membrane, and thus allowing the air to escape from the lungs, as in oblique external wounds, where the outer opening, and that of the pleura costalis have healed, or closed up, and in ulcers of the surface of the lungs.

2dly. "The pleura pulmonalis, and pleura costalis, may be wounded or ulcerated, when there is no external opening, as when the ends of fractured ribs penetrate through both into the substance of the lungs; and it is from this accident, &c. that emphysema most commonly takes place.

3dy. "The common integuments of the parietes of the chest, the intercostal muscles, and the pleura costalis, may be wounded, while the pleura pulmonalis and the lungs remain uninjured, so that the air admitted from without, and collected in the cavity of the thorax, may be pressed into the cellular membrane, so as to occasion emphysema."

Dr. Halliday shortly afterwards remarks, "that the lungs in the thorax, have often, and not unaptly, been compared to a bladder in a close pair of bellows; but if we suppose the bellows to be divided into two compartments, and each of these to contain a bladder, which mutually communicate with each other, and with the external air, by means of a tube,

which is exactly adapted to the nozzle of the bellows, and which admits the air only into the cavity of the bladders, and not in the space, betwixt the bladders and bellows, we shall then have a perfect representation of the mechanical structure of the thorax. The bellows will represent the thorax, divided in the middle by the mediastinum; the bladders will represent the lungs of the right and left sides; and the tube, which communicates with the bladders and with the external air, will represent the trachea. The only thing, which is wanting to render this mechanical representation perfect, is, that the bladders should exactly fill the bellows, so as to leave no air betwixt them and the bellows."

Dr. Halliday notices, that when we lift up the handle of the bellows, the bladders become filled by the external air, which rushes in through the tube, which communicates with both of them. When the handle is depressed, the air is expelled again. In the like manner, the lungs are filled with air, and emptied again when the capacity of the chest is enlarged by the inspiratory muscles, and then diminished by the expiratory ones.

When emphysema arises from a wound, or ulceration of the pleura pulmonalis, on one side of the thorax, the case is nearly the same as if an opening were made in one of the bladders, which opening would form a communication, as Dr. Halliday observes, with the bellows and bladder on one side. If this should happen, while the handle of the bellows is depressed, no sooner is the handle raised, than air rushes into the space, betwixt the bladder and bellows, and, on keeping up the handle a little while, the bladder will become quite collapsed, and the place which it occupied, while distended, will now be occupied by the air. If now, says Dr. Halliday, "we attempt to force out the air, by depressing the handle of the bellows, we shall find that this cannot be done; for, there is no direct communication, between the bellows and the external air; and, as the effused air presses equally on all parts of the collapsed bladder, it cannot escape through it."

When the thorax is expanded in inspiration, the pressure is taken off the surface of the wounded lung, and the air, which now enters this organ, instead of distending its cells, passes through its wound into the space between the pleura pulmonalis, and pleura costalis. The lung will, indeed, be partially expanded, as long as inspiration on that side goes on; the more so, the smaller its wound is. At every expiration, however, when the thorax is diminished, the effused air will be compressed against the wounded lung; but none of the air, which has escaped, can re-enter the lung again; "because

(as Dr. Halliday accurately remarks) the whole of the air contained in the lung must be forced out, and then the pressure (of the air) against every part of the collapsed lung being equal, will prevent its separating any part, so as to make a passage for itself into the trachea." Thus fresh air accumulates at every inspiration in the space, between the pleurae, while none can escape from the same situation during expiration, and the quantity accumulated will, at last, equal that which is received into the other lung, during the most powerful inspiration. Dr. Halliday notices, that some authors have termed this case *thoracic emphysema*; it is clearly attended with no diffusion of air in the cellular substance, a circumstance, generally implied, when we speak of emphysema.

When both the pleura pulmonalis, and pleura costalis are wounded, the same effusion of air between these two membranes continues to take place, from the abovementioned causes, till the lung is collapsed. When an attempt is now made to expire, the injured side of the thorax must continue distended, notwithstanding every effort of the patient. However, when, in this expiratory act, the capacity of the thorax is diminished, and the air compressed, a part of it finds its way, through the wound in the pleura costalis, into the common cellular substance of the parietes of the chest.

The passage of air into the cavity of the thorax during inspiration is, as Dr. Halliday observes, now more easy, than the return of that, which is already effused in the cellular membrane, and consequently, the *subcutaneous emphysema* continues to increase with a rapidity, which is remarkable, as long as the patient lives.

To explain the origin of emphysema, in cases of wounds, which only enter the chest, and do not injure the lungs at all, Dr. Halliday has recourse to the simile of the bellows, and bladders. Were an opening made into the bellows, without injuring the contained bladders, if the access of air by this opening be more free, than that by the nozzle, communicating with the cavity of the bladder, more air will enter by the opening, than by the pipe, on the handle being raised, so that the bladder will not rise as before, when no opening in the side of the bellows existed. If the latter opening be smaller, than that of the pipe, the bladder will only be partially filled, and, on depressing the handle of the bellows, the air, contained in the bladder, and that between the bladder and the bellows, will be expelled, in the same proportion to each other, as that, in which they were formerly filled. This process would continue to go on in the same way, did not

the bladder naturally collapse more and more from its gravitation. Let us now stop the mouth of the pipe, while the handle of the bellows is raised, and the bladder partially filled. On trying next to depress the handle, it results, that, as no air can escape from the pipe, that air, which is contained between the bladder and the bellows, must be first evacuated, while that, contained in the bladder of the sound side, will be forced into the bladder on the injured side, and either distend it, so as to rupture it, or cause it to protrude.

Hence, in the case of a wound, penetrating the chest, without injuring the lungs, if the air can enter more freely by the wound, than by the trachea, more of it will enter, in the act of inspiration, into the cavity of the thorax, than into the lungs. On the contrary, when the opening of the wound is not so large as that of the trachea, less air will enter the thorax, than the lungs.

In expiration, the air will be expelled from the two different situations, in proportion to the quantity, which enters each of them in inspiration, and, no air at all would accumulate in the thorax, did not the lungs always tend to collapse from their gravitation. Should, however, the patient, in making an effort to expire, contract the glottis, the air, contained in the lungs of the sound side, may be propelled into the bronchia and air-cells of the lungs, on the same side as the wound, so as to distend them, and even make them protrude at the wound.

Dr. Halliday remarks, that such a protrusion often happens, when wounds are made in dogs, and has been erroneously adduced as an argument against the collapse of the lungs, when an opening is made into the thorax of the human subject. (See *Observations on Emphysema*, by A. Halliday, M. D. 1807.)

For information, concerning the treatment of the affection, the reader is referred to the article *Emphysema*, in this Dictionary.

5. We have already noticed, that wounds of the thorax may injure one of the intercostal arteries, and when the blood cannot find free vent outward, it may become extravasated in the cavity of the chest. The same consequence may follow wounds of the pulmonary vessels, those of the heart, or of the heart itself. When the hemorrhage, however, takes place from vessels above a certain size, the wounded person dies almost instantaneously; but, when they are not so large, he may live for a greater or less time, and receive the succour of surgery.

The following are the symptoms, which denote an extravasation of blood in the thorax. The patient feels great oppression, and such uneasiness as will not let

him long continue in one position. He experiences much difficulty, in standing up, or sitting up in his bed, unless he bends his body very much forward, in which position, the diaphragm is relaxed, and not so much dragged by the weight of the extravasated fluid. When the thighs are bent, the patient can lie with tolerable ease on his back; he is also not averse to lying on the side, on which the wound is situated; but, he cannot place himself on the opposite one, without feeling very acute pain in the situation of the mediastinum.

His respiration is short, frequent, and interrupted by sighs; his veins become empty; a mortal paleness spreads over his countenance; his extremities become cold; a viscid perspiration covers his neck and temples; his teeth chatter; his pulse becomes weak, and if, as most frequently happens, the lungs are wounded, he spits up frothy blood, and air issues from the wound.

Though one might suppose the above class of symptoms were always attendant on a considerable effusion of blood in the thorax, yet they are not so. Wounded persons have been known to die of such an extravasation, whose respiration was tolerably free, and who did not complain of suffering more inconvenience in one posture than another. Sabatier says, that several facts of this kind have fallen under his own observation. Other wounded persons, also, who have suffered most of the complaints ascribable to extravasations of blood in the thorax, have been cured by ordinary means. M. Mery gives an account of a young man, wounded in the anterior and superior part of the chest, about two o'clock in the morning, who had such difficulty of breathing, and so much fever, five hours afterwards, that M. Mery was of opinion, that an extravasation had happened, and he was thinking of making an opening for the evacuation of the blood. A tumour, which originated near the great pectoral muscle, and presented, neither the feel of fluctuation, nor that of emphysema, made him suspend his decision. Some bleedings, and the application to the tumour of compresses, dipt in a mixture of spirit of wine and water, dispersed the symptoms. This recital shews, as M. Mery has remarked, how equivocal the symptoms of an extravasation in the chest are; how difficult it is to form an opinion; and how liable to failure any operation is.

However, even the assemblage of the above symptoms, did not lead M. J. L. Petit into a mistake. Having been requested to assist at an operation, which was about to be done on a wounded man, about whose armpit, pectoralis major, and latissimus dorsi muscles, a prodigious emphysematous swelling had taken place;

whose respiration was painful and difficult; and who spit up frothy blood from his mouth; M. Petit gave it as his opinion, that it was unnecessary to make an opening into the chest. He thought, that it would be sufficient to enlarge the wound, which was at a little distance from the armpit, near the edge of the latissimus dorsi, so as to give vent to the effused air. This advice having been followed, the emphysema in a little while disappeared, and the patient soon recovered.

The equivocal nature of the symptoms of extravasations of blood in the thorax, has induced practitioners to pay the most scrupulous attention to every circumstance attendant on these cases. Valentine remarked, in several instances, that a few days after the wound, an ecchymosis occurred, at the angle of the false ribs, and spread towards the loins. The ecchymosis is described as being of a clear purple colour, like the spots, which sometimes form on the abdomen, a little while after death. Such is the difference, between this ecchymosis and that, which consists of an extravasation of blood in the cellular substance, from the rupture of blood-vessels, which makes its appearance shortly after the accident, begins close to the injury itself, and is of a deep colour, commonly spotted with some red points. Valentine advised a counter-opening to be made, in a case, in which most of the symptoms of extravasation were combined with the above sort of ecchymosis. The advice was overruled, and the patient soon afterwards died. More, than six pints of blood, were found extravasated in the thorax.

Sabatier remarks, that we cannot too highly applaud the zeal of those practitioners, who endeavour to dispel the doubts, which still prevail in several parts of surgery. At the same time, he thinks, that all, who take interest in the improvement of this science, should endeavour to ascertain the truth of any new observations, which are offered. Hence, he deems it proper to relate a case, which was communicated to him by M. Saucerotte (the father) an eminent military surgeon, and which shews, that the ecchymosis, observed by Valentine, is, at least, not invariably attendant on extravasations of blood in the chest. A carabinier, who had received a thrust with a sabre in the right side of the thorax, above the tendon of the pectoralis major, appeared to be going on very well for the first four days following the accident. On the fifth, he complained of difficulty of breathing, uneasiness, and an inability of lying on the left side, without aggravating his complaints. He complained of a great deal of pain in the region of the liver, and at the top of the shoulder. His pulse was small and contracted, and rather hard, than weak. The right side of the

chest seemed larger, than the left. On the eighth and ninth day, the symptoms became more urgent, and the patient found no ease, except in leaning on his right side, and supporting himself on a chair, placed across his bed. This assemblage of symptoms indicated an extravasation of blood in the right cavity of the thorax; but, as the ecchymosis, which M. Valentine has described, was not apparent, M. Saucerotte thought that they might be deceitful. Their long continuance, however, had made him resolve to make a counter-opening, but, in the mean while, the patient died, in the night between the ninth and tenth day. When the operation was done on the dead body, a pint of putrid blood flowed out.

When the surgeon feels assured, that an extravasation of blood in the thorax has really occurred, the only indication is to make an opening for its escape. However, before undertaking this operation, the revived state of the pulse, the return of warmth in the extremities, and the cessation of convulsions, ought to denote, that the hemorrhage no longer continues from the wounded vessels. If this were not the case, a fresh quantity of blood would soon be extravasated, and the patient die exhausted. Besides, by delaying to make an opening for the discharge of the blood, we give nature time to employ her own resources. Observers have recorded instances, in which extravasations of blood in the thorax have got well, without any operation. Fabricius ab Aquapendente relates an example of a man receiving so narrow a wound in the chest, that it was impossible to make out, whether it had penetrated the pleura, or not. The spitting of blood, weight on the diaphragm, fever, and oppression, with which the patient was soon seized, removed all uncertainty. It was determined to make an opening into the chest, when a large glassful of blood came away with the urine; the pain now subsided, the fever and other complaints abated; and a speedy recovery followed.

Though Fabricius sets this case down as one of extravasation, and that it was cured, in consequence of the evacuation of blood with the urine, both inferences may, at all events, be rationally questioned.

Authors make mention of five methods of discharging collections of blood in the thorax; viz. 1st. By placing the patient in a posture, which favours the escape of the blood; 2dly. By introducing a syringe for the purpose of sucking it out, or a mere cannula, through which it is to flow; 3dly. By enlarging the wound; 4thly. By employing injections; 5thly. By making an opening into the thorax in a depending situation.

1. Success cannot be expected from

merely placing the patient in a posture, which is favourable to the escape of the extravasated blood, except when the wound is situated at the inferior part of the chest, and is large and direct in its course. Paré successfully adopted this method in the case of a soldier, who was stabbed in three places with a sword, one of the wounds, which entered the chest, being situated under the right nipple. The man was first dressed by a surgeon, who made several sutures. The patient was soon afterwards attacked with considerable difficulty of breathing, fever, coughing, spitting of blood, and acute pain in the side. Paré, who was consulted the next day, suspected, that an extravasation had happened: consequently, he cut out the sutures, and placed the patient in a position, in which his feet were much more raised, than the head. Paré also recommended him to hold his breath, and then introduced his finger into the wound, in order to take away some clots of blood, which appeared at its orifice. By these steps, the discharge of seven, or eight ounces, of fetid, coagulated blood, was effected. Injections of barley-water, in which were mixed a little honey of roses and sugar-candy, gave the patient ease, and finished the cure.

2. The idea of sucking out of the cavity of the thorax, by means of a syringe, blood extravasated in this situation, was conceived a long while ago. The pipes of all syringes, for this purpose, should have blunt ends, lest they injure the lungs. Mere tubes, containing a stilet, have also frequently been employed. In the cases, related by Scultetus, there is an example, in which an instrument of the latter sort was successfully made use of. No syringe, nor any suction with the mouth, was requisite; it was only found necessary to introduce the tube, and then withdraw the stilet.

Lamotte used only a simple cannula, which he introduced into the centre of the extravasation. Then having placed the patient in what he conceived to be the most favourable posture, and requested him to hold his breath, he drew off the collection of fluid. The cases, numbered 216, 217, 218, shew the success, which attended this method. Although it might also have answered very well in case 219, Lamotte saw, that the exceedingly high situation of the wound would not have allowed all the blood to be discharged, and, therefore, he made a counter-opening. Thus the thorax was completely emptied, and a recovery the consequence. When a cannula is employed, authors recommend it to be introduced every day, till the bad symptoms cease, and no more fluid escapes through the cavity of the instrument. After having given vent to

blood, it allows a bloody serous fluid to escape, and at a later period pus, which becomes of a thicker and thicker consistence, the nearer the patient is to a recovery.

3. The cases, in which an enlargement of a wound, complicated with an extravasation in the chest, should be practised, are those, in which there is reason for thinking, that the situation is favourable for the escape of the blood. The operation is performed by introducing a grooved director, along which the knife is to be guided. The integuments, and external muscles, are to be divided in a perpendicular direction, and the intercostal muscles in a line parallel to the ribs. Care is also to be taken not to cut too near the lower edge of the upper rib, lest the intercostal artery be wounded. Dionis relates, that he practised such an operation on a soldier, who was wounded at Béfort in 1703, by the thrust of a sword below the right nipple, which made a direct opening into the thorax. As the patient was half a league from the town, his chest had become full of blood, before he could be assisted. When the extravasated fluid had been let out, Dionis made the patient lie on the wounded side, during the night, and in proportion as the blood continued to be thus evacuated, the breathing became free from oppression. The next day, the thorax was quite emptied, and the cure was so speedy, that the patient was in a state to join the army, a month afterwards.

4. The methods, which have just been explained, may be of use, when the blood retains its natural state of fluidity; but, when it has coagulated, as often happens, they can be of no avail. In this circumstance, the best plan, which can be adopted, is to inject warm water into the chest, which injection is the best calculated for loosening, and dissolving the coagula, and washing them out of the wound. A proper opening must, of course, be previously made. The French writers, even the modern ones (*Sabatier*) most absurdly recommend the injection of various detergent vulnerary decoctions, and of solutions of honey of roses, soap, salt, &c. What idea these authors can entertain of the great sensibility and tendency to inflammation of the lungs and pleura, or what good they can expect from such applications, is difficult of conception. I am firmly convinced, that the meanest scribbler on surgery, in this country, would be ashamed of being an authority for such advice.

5. When the wound is narrow, and situated at the upper part of the chest, we cannot expect to be able to give vent to the extravasated blood, without making a counter-opening at the lower part of this

cavity. The best place for making the opening, and the proper manner of executing the operation, are explained in the article, *Paracentesis of the Thorax*.

When the opening has been made, the blood makes its escape. Its exit is to be promoted by placing the patient in a posture, which makes the opening as depending as possible, and by desiring him to hold his breath.

After as much blood, as can be obtained, has been taken out, the common plan has been to maintain the opening, and not let it heal, till after a certain time.

For this purpose, the old surgeons used to employ tents, made of lint, which were proportioned to the size of the opening, being short, soft, and flattened. They had a sort of head, and a double ligature attached to them, and were often dipped in different kinds of applications. Tents have now been quite abandoned, as they are apt to bring on an inflammation of the lungs, hinder the escape of whatever fluid is contained in the chest, and cause great irritation, pain, and even exfoliations from the ribs.

Others have recommended introducing the end of a kind of wick, which, they contend, keeps open the wound, without hindering the escape of fluids. Such advice, however, is not free from objections, nor is the latter reason altogether true.

Le Dran preferred tents to wicks: he states, that the hemorrhage can only be stopped by the coagulum, which forms over the mouth of the wounded vessel. The clot is elongated, and even continued into the vessel itself, and while it remains there, no more blood is effused. In the mean while, it flows into the collateral vessels; and the mouth of the vessel closes, and includes within its parietes, the portion of the coagulum, which has formed in it. Thus the clot becomes gradually separated into two portions, one of which remains in the vessels, and acts as a sort of plug, while the other is detached with the suppuration. Hence, continues Le Dran, when a tent is introduced into the opening, which has been made, it must confine a part of the blood, which has been extravasated into the chest, and without which portion being retained, the clot would not be supported, but fall off, before the mouth of the vessel had closed, and the hemorrhage constantly continue. Without entering into an examination of Le Dran's theories of the stoppage of bleeding, a subject, which is fully explained in the article *Hemorrhage*, we may only remark, that this author's predilection for the use of tents is founded on a supposition, that the counter-opening has been made, before the hemorrhage from the vessels has ceased. Every one, however, agrees, that no steps should be

taken for the discharge of the blood, contained in the thorax, before being assured, that the hemorrhage has ceased. Hence, the tent can only be regarded as hurtful. But, dismissing from consideration wicks and tents, the best means of maintaining an opening, (were such thing necessary, which cannot frequently be the case,) would be, a short cannula, with a rim to keep it from slipping into the thorax, and two little rings for confining it in its situation with a ribband. This should only just enter deeply enough to have its inner orifice on a level, or a very little further inward, than the pleura costalis, so that it may not injure, nor irritate the lungs. A plug should be kept in its outer opening, and withdrawn, as often as occasion requires, that is, as often as any material quantity of fluid collects, and requires to be discharged.

When the patient has been dressed, he is to be kept in bed, with his head and chest somewhat elevated, and his thighs bent, in which position, the breathing will be found to be least oppressed. It is usual also to recommend him to lie, as much as possible, on the side on which the operation has been done. He is to keep himself in as still, and quiet, a condition as he can. He is to be put on very low diet, and, if his strength allows, he is to be bled, and this evacuation repeated, with other antiphlogistic means, as often as the urgency of the fever and inflammatory symptoms indicates, and the strength of the constitution allows. Bleeding from the arm, besides counter-acting inflammation in the chest, which is a principal source of danger, does good by lessening the force of the circulation in the wounded vessels, and thus it diminishes the tendency to internal hemorrhage.

In keeping open wounds of the chest, the surgeon must be careful, that no tents, nor any of the dressings, glide into the cavity of the pleura. Numerous cases on record shew the necessity of using great caution, that no accident of this kind occur. Tulpius makes mention of a Danish gentleman, who had been under a careless surgeon, on account of a wound in the thorax, and who coughed up, six months afterwards, a large tent. A similar fact is recorded, among the cases collected and published by Fabricius Hildanus. A man was stabbed with a sword in the right side of the chest, near the axilla, between the second and third ribs. A great deal of blood was discharged, during the first fortnight, both from the wound, and by the mouth. The wound was successfully healed; but, the patient continued to suffer considerable difficulty of breathing, and an incessant cough, and he used to spit up a greenish, fetid matter. Three months afterwards, he coughed up two tents,

which had slipped into the cavity of the thorax, from beneath the dressings, with which the wound had been covered.

In whatever condition the patient may be, any change in the antiphlogistic regimen must be made with very great circumspection. Too much nourishment, talking too frequently, and any exertion, are circumstances, which may induce a renewal of the hemorrhage, and extravasation, even after a considerable time. Vesalius saw an accident of this nature happen, a fortnight after the wound, and eleven days after the operation for empyema. A Biscayan soldier, who had been stabbed in two places with a sword above the right nipple, was attacked by fever, difficulty of breathing, restlessness, and acute pain at the bottom of the chest. These symptoms induced Vesalius to infer that an extravasation had taken place; but, he was afraid of making an opening into the chest, for fear the hemorrhage should still continue from the wounded vessels. However, as the patient remained in the same state, the fourth day after the receipt of the wounds, and his strength still lasted, Vesalius undertook the operation, by which a considerable quantity of extravasated blood was discharged. The patient felt great relief at the instant. The oozing of blood continued for a few days, after which a favourable suppuration took place in all the three wounds, and the case was, therefore, expected to end well. But, the patient having regained his strength, and taken too much food, the recurrence of hemorrhage caused his death, at the very time when he seemed to be getting well. M. Lombard, well known for some excellent productions on surgery, saw a soldier die instantaneously of internal hemorrhage, from throwing a bowl at some nine-pins, two months after he had been cured of a wound of the chest and lungs.

Authors in general advise us, before we close the wound, for the purpose of healing it, to make the patient expel the air from the chest. For this object, they advise the patient to be requested to make a strong inspiration, with the wound closed, and then a long slow expiration with it open, and so on, till as much of the air as possible is discharged, and then the wound is to be accurately closed with sticking plaster. From what we have said, however, in the article *Emphysema*, it will appear, that when there is a direct opening into the thorax, so as to admit the external air, the lungs on one side collapse, and remain so till the wound is healed, and the air absorbed. When one of these organs is wounded, a collapsed state is, indeed, the best condition, in which it can possibly be for a certain time, that is, till the breach of continuity in it has healed. All

efforts to make the lung expand, by exhausting the air from the cavity of the pleura, seem unavailing; but, there is certainly no objection to not closing the wound, before as much air has been expelled in the above way, as can be thus got rid of.

Fistulae sometimes continue for a long while after wounds of the thorax. Felix Platner mentions an instance, in which a man had in his chest a fistulous opening, out of which the air rushed with such force as to blow out a candle. He lived a long while with this disease, without suffering any particular inconvenience.

Another occasional consequence of openings made in the chest, is a hernia of the lungs, an affection, of which, Sabatier says, he is not aware, that any one has spoken. This gentleman, however, has seen such a case. A soldier, thirty years of age, who had been wounded at Rostock with a bayonet, in the right side of the chest, between the middle part of the fifth and sixth true ribs, had several bad symptoms which he survived. The wound was successfully healed; but, as the intercostal muscles had been divided to a great extent, and could not be approximated with precision, there remained an empty space under the integuments, which allowed a piece of the lungs, as large as a walnut, to protrude between the ribs. The swelling enlarged at the time of inspiration, and grew smaller when expiration took place. It only occasioned a slight pain, without any oppression in the chest.

The making of an opening into the chest, as already spoken of, is recommended, as Sabatier remarks, by all authors, who have treated of wounds of the chest. However, it does not appear, that the operation has been often done. Few instances are to be met with on record. J. L. Petit does not make mention of even one. Lamotte, who had the care of an infinite number of patients, never practised the operation, except twice, and, in one of these instances, it was done to let out a collection of matter in the thorax, which had occurred after a wound, which injured the lungs. Sabatier notices, that the seven volumes of the *Journal de Médecine Militaire*, which contain a collection of the most interesting cases, which have presented themselves in the military hospitals, record no example, in which it was necessary to resort to the operation in question. No instances are related in the *Mém. de l'Acad. de Chirurgie*. Sabatier says, he has enquired of many army-surgeons; but, none of them have either seen the operation done by others, or performed it themselves. M. Saucerotte, observes Sabatier, is the only one, who did it with success in a case, in which the exigency for the operation would not be expected. It was in an instance of a gun-shot wound. The necessary dilata-

tions, and the extraction of extraneous substances, had diminished the inflammatory symptoms. These were subsiding entirely, when, on the third day, a violent hemorrhage took place from one of the branches of the internal mammary artery. This loss of blood, together with repeated venesections, did not hinder a considerable extravasation of blood in the chest from happening on the fifth day. The patient was threatened with suffocation. He was directed to bend forward, in order to promote the escape of the fluid, of which about a pint, in colour like wine-lees, and having a disagreeable smell, was discharged. A considerable quantity was in this way evacuated, every morning and evening. The posture, in which the patient was necessarily put, and the efforts he was obliged to make to promote the evacuation, fatiguing him exceedingly, he consented to have a counter-opening made, at the lower part of the chest, on the eighteenth day. The operation gave vent to a pint of blood, of the same kind as that which had issued from the wound. The quantity emitted became daily less and less, and, in three months, the patient got quite well. Sabatier questions, from what has been stated, whether we may not conclude, that the extravasations of blood in the thorax, which admit of surgical aid, are exceedingly unfrequent cases, and that the symptoms, indicative of these instances, are not sufficiently clear, so that most of the patients, with such extravasations, die, without it being possible to make any attempt to save them. (See *Médecine Opératoire*.)

WOUNDS OF THE ABDOMEN.

In such cases, we find, that one of the chief causes of danger is the tendency of the peritoneum to inflame. Every wound which penetrates the belly is apt to excite this inflammation, and every inflammation, however slight, is prone to spread, to extend itself over all the viscera, and to terminate in gangrene and death.

There are (says Mr. John Bell) a thousand occasions, on which the delicacy of the peritoneum may be observed. The wound of the small sword, and the stab of the stiletto, explain to us, how quickly the peritoneum, and all its contained bowels, inflame from the most minute wound, although the injury be almost too small to be visible on the outside, and scarcely within; for, often, upon dissection, no intestines are discovered wounded, and no feces have escaped into the abdomen. In subjects, who die after lithotomy, we find the cavity of the peritoneum universally inflamed. The operation of the Cæsarean section is fatal, not from any loss of blood, for, there is little bleeding; nor, from the

parts being exposed to the air, for, patients also die, in whom the womb bursts, and where the air has no possible opportunity of insinuating itself; but, the case proves fatal from the inflammation, which is always disposed to originate from wounds of the peritoneum, small as well as great. (*Discourses on the Nature and Cure of Wounds*, p. 310, edit. 3.)

But, although there can be no doubt that the wound, abstractedly considered, is the most frequent occasion of this dreaded inflammation; yet, it sometimes happens, that the inflammatory consequences must be ascribed to another kind of cause. If an intestine be wounded, its contents may, under certain circumstances, be effused in the abdomen; if the liver, spleen, kidney, or any large vessel be injured, blood may be poured out amongst the viscera; if the gall-bladder be wounded, bile may be effused; and, if the bladder be pierced, the urine may escape into the abdomen. Now all these extravasated fluids are extraneous substances, with respect to the surfaces, with which they have come into contact, and they usually give rise to inflammation of the peritoneum and viscera.

Wounds of the belly are divided, by almost all writers, into such as penetrate the cavity of the abdomen, and into others, which only interest the skin and muscles.

The former differ very much in their nature, and degree of danger, according as they do, or do not, injure parts of importance, contained in the peritoneum. The latter are not remarkably different from the generality of other superficial wounds. The chief indications are to lower inflammation, and to prevent collections of matter. A few particularities, however, in the treatment of superficial wounds of the abdomen, seem to merit attention.

SUPERFICIAL WOUNDS.

The most ancient surgeons, and their successors, regularly up to the present day, have recorded, that wounds of tendinous parts frequently give rise to very unpleasant consequences. Almost the whole front of the abdomen is covered with tendinous expansions, and, on this account, it is not unusual to see punctured wounds in this situation followed by extensive inflammations, and the formation of abscesses. The patient is, at the same time affected, with a great deal of inflammatory fever. (See *Fever*.) He suffers acute pain, sickness, hiccough, and considerable disturbance of the nervous system. (*Callisen, Syst. Chirurg. Hodiernæ*, p. 698, *Hafnia*, 1798, *Vol. 1.*) When the tension and swelling of the abdomen abate, shiverings sometimes occur, and indicate the occurrence of suppuration.

The matter, which forms in these cases,

sometimes accumulates in the tendinous sheath of the rectus muscle, and, when the collection in this situation remains undiscovered until a pointing appears, no sooner does the abscess burst or is it opened, than an extraordinary quantity of matter is discharged. The surgeon should carefully remember the nature of this kind of disease, as there is frequently no alteration in the appearance of the integuments to denote, either the existence, or the extent, of the suppuration.

Such an abscess forms one remarkable exception to the excellent general rule of allowing acute phlegmonous abscesses to burst of their own accord. In the present instance, there is an aponeurotic expansion, intervening between the abscess and the skin, and nothing retards the natural progress of the matter to the surface of the body so powerfully, as the interposition of a tendinous fascia. But, even in this circumstance, the propensity of pus to make its way outward is often seen to have immense influence. Though there is only a thin membrane, (*viz.* the peritoneum) between matter so situated, and the cavity of the abdomen, yet, in time, the abscess mostly points externally.

The proper treatment of this case is to prevent the surprising accumulation of matter, and rapid increase of mischief, by making a depending opening, sometimes at the very lowest part of the sheath of the rectus muscle, and this, as soon as the lodgment of matter is clearly ascertained.

If ever there be a case, in which it is advantageous and justifiable to make an early dilatation of a punctured wound, in order to prevent the above-described ill-consequences, it is unquestionably the present one. Such practice, indeed, is advised by the judicious Callisen, in addition to the strictest antiphlogistic means. (*See Syst. Chir. Hodiernæ, Vol. 1, p. 698, edit. 1798.*)

The matter sometimes forms between the external and internal oblique muscles, and spreads most extensively. The pus may even insinuate itself into the abdomen, and the case end fatally. Such an example is recorded by Dr. Crowther, of Wakefield. In this instance, however, the disease proceeded from a contusion, not a wound. (*See Edinb. Med. and Surgical Journal, vol. ii. p. 129.*)

Superficial wounds of the abdomen are to be treated on the same principles, as similar wounds in other situations. The indications are to prevent inflammation as much as possible, and, if suppuration should be inevitable, to let out the matter by a depending opening, as soon as the abscess is known to exist. The inflammation is to be checked by general and topical bleeding, low diet, emollient clysters, diluent beverages, quietude, opening medicines,

cold applications, or fomentations and poultices, and the mildest, and most simple dressings. (*See Inflammation.*)

Whenever the abdominal muscles are wounded, it is desirable to relax them; but this object should not lead us to put the patient out of a horizontal position. A very important point, in the treatment of wounds, which interest the parietes of the abdomen, is to afford a certain degree of support to the wounded part, when there seems any chance of their being too weak to resist the pressure of the viscera. The parietes of the abdomen are almost wholly composed of soft parts, which easily yield. No part of the front, or sides, of the abdomen, is supported by the stability of a bony structure, and, as the viscera are, for the most part, more or less moveable, and closely compressed by the abdominal muscles, and diaphragm, they are extremely liable to protrude, whenever the resistance of the parietes of the abdomen is not sufficiently powerful. Thus very perilous cases of herniæ may originate.

For the above reasons, all wounds of the abdomen, especially those, in which both the integuments and muscles have been cut, demand strict attention to the precaution of supporting the wounded part, and this, though the peritoneum itself should not happen to be divided. The patient ought to keep as much as possible in a horizontal position, while suitable compresses and bandages should be applied to the situation of the wound. In order to guard against the occurrence of herniæ, the part should be supported, in this way, a considerable time after the wound is healed.

The peritoneum being connected by means of cellular substance, with the inner surface of the abdominal muscles, there is always some risk of the inflammation of these muscles extending to the membranous lining of the abdomen. This occurrence must be averted by the rigorous employment of the antiphlogistic treatment. What renders the event still more dangerous, is, that when one point of the peritoneum is affected, the inflammation usually spreads with immense rapidity over its whole extent, and too often proves fatal.

As superficial wounds of the abdomen are to be treated on the general principles, applicable to all similar wounds in other situations, it is hardly necessary to state, that union by the first intention is always to be attempted, when possible.

OF WOUNDS PENETRATING THE CAVITY OF THE ABDOMEN.

In these cases, the first thing, which the surgeon is generally anxious to know, is, whether the wound penetrates the cavity of the abdomen, and whether any of the viscera are probably injured.

When the wound is extensive, and any of the bowels protrude, the first part of the question is at once decided. But, when the wound is narrow, and allows none of the viscera to protrude, it is often exceedingly difficult to ascertain, whether the injury extends into the abdomen, or not. An opinion, however, may usually be formed, by carefully examining the wound with one of the fingers, or a probe, after having put the patient, as exactly as possible, in the posture in which he was at the time of receiving the accident; by observing, if possible, the shape and dimensions of the instrument, with which the injury was done; how much of the weapon entered the flesh; the direction in which it was pushed; by attending to the quantity of blood, which the patient has lost, the state of his pulse, &c. and, lastly, by observing, whether there is any discharge of bile, feces, or other fluids, known to be naturally contained in some of the abdominal viscera.

When the wound is sufficiently large to admit the finger, we may always ascertain whether the injury extends into the cavity of the abdomen, because the viscera may then be easily felt. There is only one chance of deception, and that arises from a possibility of the practitioner's mistaking the inside of the sheath of the rectus muscle for the cavity of the peritoneum. When the examination is made with a probe, we should be particularly cautious in forming a judgment; for, the parts are so soft and yielding, that a very little force will make the instrument pass a considerable way inward. Every examination of this kind should always be undertaken, if possible, when the patient is exactly in the same position, as he was at the time of receiving the wound.

Injections have been employed for ascertaining, whether wounds penetrate the cavity of the abdomen. This absurd experiment, however, has now been most justly exploded from practice. It is well known to the moderns, that the space termed the cavity of the abdomen, is, in fact, completely filled with the various viscera, and that a fluid would, in general, not so easily find its way into the bag of the peritoneum, as an unreflecting person might suppose. If the injection were propelled with much force, it would be quite as likely to insinuate itself into the cellular substance of the parietes of the abdomen, or, perhaps, into the sheath of the rectus muscle. The least tortuosity of the wound, or a piece of bowel, or omentum, lying against the internal orifice of the injury, would completely prevent an injection from passing into the abdomen.

When a considerable quantity of blood issues from a wound of the abdomen, we may pronounce, almost with certainty, that some large vessel, within its cavity, is in-

jured. Excepting the epigastric artery, which runs on the forepart of the abdomen, along the inner surface of the rectus muscle, there is not one very considerable vessel, distributed to the muscles, and integuments. At the same time, it is deserving of particular notice, that a large artery may be opened in the abdomen, and, yet, not a drop of blood may be discharged from the external wound. A copious quantity may accumulate in this manner, even without there being any palpable swelling of the belly.

In such cases, the subsequent symptoms quickly lead us to suspect what has happened. The patient complains of extreme debility and faintness; his pulse falters; he has cold sweats; and, if the bleeding should not speedily cease, these symptoms are, in general, soon followed by death.

Sometimes, the first glimpse is enough to shew, that the wound extends into the cavity of the abdomen. The event is indicated by the escape of chyle, bilious matter, feces, or other fluids, known to be contained in some of the viscera. The same information may also be obtained from seeing a considerable quantity of blood vomited up, or discharged by stool. The urine, however, may flow from a wound, which does not actually penetrate the abdomen, for the kidneys, ureter, and bladder may be said to be out of the abdomen, because they are really on the outside of the cavity of the peritoneum.

When no symptoms of the above description occur, when neither the finger, nor probe, can be introduced; when none of the fluids, known to be contained in the various receptacles in the abdomen, are emitted from the wound; when the pulse remains natural, and the pain is not excessive; there is reason to hope, that the wound has not injured parts of greater consequence than the integuments, and muscles. (*Encyclopédie Méthodique, Partie Chirurgicale. Art. Abdomen.*)

We have now taken a survey of such criteria, as are commonly noticed by surgical writers, for the purpose of instructing the reader how to discriminate a wound which has penetrated the abdomen, from one which has not. It is our next place to warn the practitioner, that too much solicitude to determine this point, is very frequently productive of serious harm. It may be set down, as an axiom in surgery, that, whenever the probing of a wound is not rendered absolutely necessary by some particular object in view, it may, in general, be judiciously omitted. A narrow, oblique wound may enter the cavity of the abdomen, without there being any particular method of ascertaining, whether it has done so, or not. This, however, is of no practical importance; for, when there are no urgent symptoms, evincing the nature of the case, the

treatment ought obviously to resemble that of a simple wound; and whether the wound be deep, or superficial, the antiphlogistic treatment is equally indicated.

The edges of a wound penetrating the abdomen, but, unattended with any obvious injury of the viscera, are to be brought together with sticking-plaster, just in the same way as common wounds. In this situation, sutures are not generally necessary. Numerous cases may be found in the records of surgery, proving that wounds of the abdomen may be easily united without sutures, if the surgeon take care to avail himself of the assistance which may be derived from a suitable position and a proper bandage. But, such cases are less decisive, than relations of the Cæsarean operation, the extensive wound of which admits of being healed by the same simple means. It is not here intended to say, that practitioners ventured in the majority of these examples to dispense with sutures altogether; but, the ligatures frequently cut their way through the skin and muscles, and the application of others was impossible, either on account of the particular state of the case, or the unwillingness of the patient. Still the union of such wounds was accomplished. A bandage, made on the same plan as that with eighteen tails, would be extremely convenient, for longitudinal wounds of the abdomen. (*Pibrac's Mém. in Mém. de l'Acad. de Chir. T. 3, 4to.*)

Sutures may not only be relinquished in the treatment of wounds of the abdomen without harm, but with benefit; for it has been proved, that their employment has brought on alarming symptoms. In one instance, the hiccough and vomiting which succeeded a wound, continued notwithstanding every assistance. On the fourth day, the wound was inflamed and painful, and it was judged proper to cut away two sutures, which had been practised, and employ only simple dressings with a view of diminishing the pain and swelling. The surgeon was not deceived in his hope; for the symptoms quickly abated, and in a week were entirely cured. The wound healed very well. (*Op. cit.*)

It must not be denied, however, that there are circumstances, in which it would be impossible to dispense with sutures. If, for instance, the belly were torn open transversely from one side to the other with a bullock's horn; or if it were extensively divided with the tusks of a wild boar, a stag's horn, a razor, &c. and the inflated intestines could not be kept from protruding; some stitches would be absolutely indicated, but even then, they should be as few as possible. (*Sabatier, Médecine Opératoire, T. 1, p. 214, edit. 2.*)

"Our good old surgeon Wiseman (observes Mr. John Bell) has said with great sim-

plicity, as a great many have said after him, "Thus, it frequently happeneth, that a sword passeth through the body, without wounding any considerable part." He means, that a rapier, or ball often passes quite across the belly, in at the navel, and out at the back, and that without one bad sign, the patient recovers, and as has very often happened, walks abroad in good health, in eight days; which speedy cure has been supposed to imply a simple wound, in which all the bowels have escaped. But, we see now, *how* this is to be explained; for, we know, that in a thrust across the abdomen, six turns of intestine may be wounded.—each wound may adhere; adhesion, we know, is begun in a few hours, and is perfected in a few days; and, when it is perfect, all danger of inflammation is over; and when the danger of inflammation is over, the patient may walk abroad; so that we may do, just as old Wiseman did in this case, here alluded to, "Bleed him, and advise him to keep his bed and be quiet." In short, a man, thus wounded, if he be kept low, has his chance of escaping by an adhesion of the internal wounds." (*Discourses on the Nature and Cure of Wounds, p. 329, 330, edit. 3.*)

When a man is stabbed, or shot in the belly, the surgeon can seldom do any good by being very officious; and the wisest conduct, that he can in general adopt, is to keep his patient as quiet as possible, have recourse to bleeding, prescribe anodynes, and the lowest fluid diet, and content himself with applying superficial dressings. In the event of severe pain and swelling of the belly coming on, leeches, fomentations, and emollient poultices will be necessary, and nothing will now avail, except the most rigorous antiphlogistic means.

SUPPURATION IN THE ABDOMEN, IN CONSEQUENCE OF WOUNDS.

Abscesses within the bag of the peritoneum are far from being common occurrences. As a late writer well observes, "the containing and contained parts of the abdomen present to each other a uniform and continuous surface of membrane. This membrane is of the serous class, and the species of inflammation, to which it is especially subject, is that, which has been denominated the adhesive. The membrane lining the intestinal canal, is of the mucous class, and the ulcerative inflammation is the species, to which this class is liable. This beneficent provision is an irresistible evidence of the operation of a salutary principle in disease. If the inflamed peritoneum had run directly into suppuration,

* P. 98. The case of a man, who was wounded across the belly, and well and abroad, in seven days.

ulceration of the surrounding parts would have been required for an outlet; and if the internal surface of the irritated bowel had tended to form adhesions, the canal would have been in constant danger of obliteration." (*Travers on Injuries of the Intestines, &c.* p. 10.)

That collections of matter, however, do sometimes take place in the cavity of the abdomen, in consequence of wounds, is a fact of which there are too many proofs on record, for the possibility of the case to be doubted. At this moment, be it sufficient for our purpose to refer to two examples of the occurrence, as related by Mr. Benjamin Bell, in his *System of Surgery*, vol. v. p. 256.

If the abscess were in any other part of the body, and did not readily point, the wisest practice would undoubtedly be to make an opening sufficient for the evacuation of the matter. But suppuration in the abdomen can seldom be ascertained with certainty, before the collection of matter has existed a good while: for, the situation of the abscess is so deep, that no fluctuation, nor swelling, becomes perceptible, until a considerable quantity of pus has accumulated. Besides, it would not be judicious to expose the patient to the hazard, which might arise from making an opening, into the abdomen, merely for the sake of giving vent to a small collection of matter.

Many, indeed almost all writers, impute a vast deal of the danger of wounds of the abdomen to the entrance of air into the cavity of the peritoneum, and they also adduce this as an argument against opening abscesses of the abdomen. In inculcating such opinions, however, they betray an inaccuracy of observation, which a very little reflection would have set right. Too much stress has long been laid on the introduction of air into the abdomen, as being a cause of inflammation. The fact is, that the cavity of the belly is always so completely occupied by the several viscera, that the whole inner surface of the peritoneum is invariably in close contact with them, and, consequently air cannot so easily diffuse itself from the vicinity of the wound, throughout the abdomen, as many have conceived. After tapping, in dropsical cases, we seldom see inflammation arise, though air has, in this instance, quite as good an opportunity of entering the abdomen, as in any case of a wound. The peritoneum in animals has been inflated, without any inflammation being excited. In cases of tympanitis, the peritoneum is distended with air, and yet both this membrane and the bowels are quite uninflamed. In the human subject, it seems probable, that, if a wound were made in a vacuum, the breach of continuity itself would lead to inflammatory consequences. We have also to remark, that collections of matter

in the abdomen are almost always completely circumscribed, and separated from the general cavity of the peritoneum, by the adhesion of the viscera to each other, and to the inside of the peritoneum.

I am of opinion, that no surgical writer has succeeded so well, as Mr. John Bell, in exposing the absurd apprehensions, not uncommonly entertained by practitioners, respecting the entrance of air into the abdomen and other cavities of the body. He enquires: 1st, Whether air can really get into the cavity of the abdomen? and 2dly, Whether, if it were there, it would produce the dreadful effects ascribed to it?

Upon the first question, his arguments run thus: "Suppose a wound of an inch in length:—suppose the bowel to have sunk, in some strange way, into the pelvis, for example, so as to have left a mere vacuum; what should happen with the flexible parietes of the abdomen? Should they stand rigid, while the air rushed into the cavity to fill it? No, surely. But, on the contrary, the walls of the abdomen would fall together, and the pressure of the outward air, far from making the air rush in by the outward wound, would, at once, lay the belly flat, and close the wound. But, since the walls of the abdomen are not flaccid, nor the cavity empty, but the abdomen full, and the flat muscles, which cover it, acting strongly, the effect must be much more particular; for, the moment that the belly is wounded, the action of the muscles will force out part of the bowels; the continuance of that action is necessary to respiration; the respiration continues as regular after the wound, as before; and the continual pressure of the abdominal muscles and the diaphragm, against all the viscera of the abdomen, prevents the access of air so effectually, that though we should hold such a wound open with our fingers, no air could pass into the abdomen, further than to that piece of gut which is first touched with the finger, when we thrust it into the abdomen. Nothing is absolutely exposed to the air, except that piece of intestine, which is without the abdomen, or that, which we see, when we expose a small piece of the bowels, by holding aside the lips of the wound. The pressing forward of that piece, and the protrusion of a portion of the gut, proportioned always to the size of the wound; the pressure from behind keeping that piece protruded, so that it is with difficulty, we can push it back with our finger; this incessant pressure, in all directions, is an absolute security against the access of air. The intestine comes out, not like water out of a bottle, the place of which must be supplied by air entering into the bottle, in proportion as the water comes out; but, the gut is pushed down by the action of the muscular walls of the abdomen, and

that action follows the intestine, and keeps it down, and prevents all access of the air whether the gut continue thus protruding, or whether it be reduced; for, if it be reduced, the walls of the abdomen yield, allowing it to be thrust back, but admitting no air. Those, who want to know the effect of air, diffused within the cavity of the abdomen, must make other experiments, than merely cutting open pig's bellies;—they must give us a fair case, without this unnecessary wound. We will not allow them to say, when they cut open the belly of any creature, with a long incision, that the inflammation arises from the air: much less shall we allow them to say, when they open the belly with a smaller incision, that, by that little incision, the air gets into the abdomen, and that all the bowels are exposed to the air." (*Discourses on the Nature and Cure of Wounds*, p. 333, 334.)

In adverting to the question, whether air is so irritating to the cavities of the body, as many have supposed, Mr. John Bell criticises, with much spirit and success, the opinions, published on this subject, by Dr. A. Monro, in his account of the *Bursæ Mucosæ*, as the annexed quotations will shew. "That the vulgar should believe, the first superficial impression that strikes them, of air hurting a wound or sore, is by no means surprising; but, it is not natural, that men, bred to philosophy, should allow so strange an assertion as this, without some kind of proof. That the air, which we breathe, and which we feel upon the surface so bland and delightful, should have so opposite a relation to the internal parts, that it should there be a stimulus, more acrid and more dangerous, than the urine, is not to be believed upon slight grounds. I do affirm, (says Mr. John Bell) that it remains to be proved, that this fluid, which seems so bland and pleasant to all our senses, and to the outward surface, is yet a horrible stimulus, when admitted, as a celebrated author grandly expresses it, "into the deep recesses of our body." (*Monro's Bursæ Mucosæ*.)

With how much reason, Mr. John Bell objects, that this doctrine is unfounded, will be manifest to every man of any discernment, or impartiality.

"The air, for instance, escapes from the lungs, in a fractured rib, and first goes abroad into the thorax; then into the cellular substance; then the emphysematous tumour appears; but, often, without any scarifications, with very little care and assistance on our part, the air is absorbed, the tumour disappears, and, without inflammation of the chest, or any particular danger, the man gets well. Here then is the air, within the cavity of a shut sac, filling the thorax, and oppressing the lungs,

without any dangerous inflammation ensuing.

"That the air may be pushed under the cellular substance over all the body, without causing inflammation, is very plain from the more desperate cases of emphysema, where the patients, after living eight or ten days, have died, not from inflammation, but, from oppression merely, the body being so crammed with air, that even the eye balls have, upon dissection, been found as tense as blown bladders. We have also many ludicrous cases of this kind, which prove this to our perfect satisfaction. Soldiers, and sailors, sometimes touch the scrotum with a lancet, introduce a blow-pipe, and blow it up to an enormous size, imitating herniæ, by which they hope to escape from the service. The old story of a man, who was so wicked as to make a hole in his child's head, and blow it up, that he might shew the child in the streets of Paris for a monster, is well authenticated; and, I have little doubt, that a fellow, who knew how to do this, would blow it up every morning, and squeeze it out when he put the child to bed at night. Some villanous butchers, having a grudge at a soldier, found him lying drunk, under a hedge; they made a little hole in his neck, and blew him up, till he was like a bladder, or, as Dr. Hunter describes the disease of emphysema, *like a stuffed skin*." (*P. 338, 339.*)

After many other pertinent observations, blended with appropriate satire, on the extravagant notions professed by Monro on the bad effects of the air, in lithotomy, operations for hernia, and hydrocele, the Cæsarean section, &c. Mr. John Bell most justly holds up to ridicule the propositions of Dr. Aitken to perform this last operation under the cover of a warm bath in order to exclude the air. "This, though it may seem to be a scurvy piece of wit, was really proposed in sober serious earnest. But (adds Mr. John Bell), the admission of atmospheric air, as a stimulus, when compared with the great incisions of lithotomy, of hernia, of hydrocele, of Cæsarean section, of the trepan, is no more, than the drop of the bucket to the waters of the ocean. And it is just as poor logic to say, that, after such desperate operations, these cavities are inflamed by the admission of air, as it would be to say, (as Monro did) that when a man is run through the pericardium with a red-hot poker, that the heart and pericardium are inflamed by the admission of the air." (*P. 347, edit. 3.*)

Enough, I conceive, has been said, to dispel all the idle fear and prejudices, which have prevailed concerning the bad effects of the air in wounds of the abdomen, as well as several other cases. When so justly eminent a man, as Dr. Alexander Monro, senior, was disturbed with such

apprehensions, it is not wonderful, that many a poor ordinary member of the profession should have been terrified nearly out of his wits upon the subject; and for quieting this alarm, and exposing its absurdities, I really think Mr. John Bell deserving of particular praise.

In general, it is an excellent rule, in all cases of wounds of the abdomen, never to be officious about abscesses, which may take place, nor concerning such viscera, as we may suspect to be injured. It is quite time enough to interfere, when the urgency of the symptoms has confirmed our conjectures. A great deal of harm is frequently done, by handling and disturbing the wounded parts more than is necessary, and, it is well known, that wounds, which are at first attended with most alarming symptoms, frequently terminate in a favourable manner. Persons have been known to have swords passed completely through their bodies, without suffering afterwards any threatening symptom, or, indeed, any effects which would authorise one to conclude, that the viscera had been at all injured. We are aware that severe inflammations may not end in suppuration, and we also know, that when pus has been formed, the fluid has been often absorbed again. Nothing then indicates the necessity for giving vent to purulent matter lodged in the abdomen, except the fluctuation and situation of the abscess be very distinct, and the quantity and pressure of the matter productive of inconveniences.

For making an opening, some writers recommend a trocar; others, a lancet. The matter must be very copious and distinct, to justify the sudden introduction of such an instrument as a trocar. It seems to me, that in all cases, the surgeon should make a cautious puncture with a lancet.

PROTRUSION OF THE VISCERA.

The omentum and small intestines are the parts most liable to protrusion in wounds of the abdomen; but in large wounds, the great intestines, the stomach, and even the liver and spleen, may project through the opening. The general symptoms indicating a protrusion of the parts are sufficiently obvious; but, it deserves attention, that, in fat subjects, the adipose membrane may project from the wound, and put on somewhat of the appearance of omentum. The special symptoms are to be collected from a knowledge of the natural situation of the parts, and reflecting what region of the abdomen is wounded. (*Callisen, Syst. Chir. Hodiernæ, T. 1. p. 702 and 703, Edit. 1798.*)

Penetrating wounds sometimes allow considerable portions of the bowels, or omentum to protrude, and, though these

viscera may not have received any injury, yet their being displaced in this way is sometimes productive of fatal consequences.

The best mode of preventing such a catastrophe, is to return the viscera into the cavity of the abdomen, as speedily as possible. Almost all authors recommend fomenting the displaced parts, before attempting to reduce them; but, in giving this advice, they seem to forget, that, while time is lost in this preparation, the protruded bowels suffer much more harm from exposure, and other circumstances, than they can possibly receive good from any application made to them. No kind of fomentation can be half so beneficial, as the natural warmth and moisture of the cavity of the abdomen. In order to facilitate the return of a protruded piece of intestine, or omentum, the abdominal muscles should be relaxed by placing the patient in a suitable posture, and the large intestines be emptied with a glyster. In mentioning the last measure, it is not meant, that the surgeon should delay the attempt to reduce the part, until the glyster has operated. No, this means is only enumerated as one that may become serviceable, in case the surgeon cannot immediately accomplish the object in view.—The mesentery ought always to be reduced before the intestine; the intestine before the omentum; but, the last protruded portion of each of these parts ought to be the first one reduced.

It is only when the intestine and omentum are free from gangrene and mortification, that they are invariably to be returned into the cavity of the belly, without hesitation. Also, when the protruded parts are covered with sand, dust, or other extraneous matter, it is undoubtedly proper to make them as clean as possible, before putting them back into the abdomen. For this purpose, the parts should be tenderly washed with a little lukewarm milk and water.

The two index fingers are the most convenient for reducing the parts, and, it is a rule to keep the portion first returned, from protruding again by one finger, until it has been followed by another portion, introduced by the other finger. The second piece is to be kept up, in the same way, by the finger used to return it; and so on, till the whole of the displaced parts have been put into their natural situation.

In attempting to reduce a piece of protruded intestine, the patient should be placed in the most favourable posture; the head and chest should be elevated, and the pelvis raised with pillows. Nothing can be more absurd, than the advice to have the thorax rather lower than the pelvis, in order that the weight of the viscera may tend to draw inward the protruded parts.

This is another erroneous idea, arising from the ridiculous supposition, that a great part of the abdomen is actually an empty cavity. The relaxation of the abdominal muscles is a much more rational and useful object. When this is properly attended to, and the wound is not exceedingly small, in relation to the bulk of the protruded viscera, the parts may generally be reduced by observing the above directions. But, in addition to what has been already stated, it is necessary to remark, that the pressure should be made in a straight direction into the abdomen; for, when made obliquely, towards the edges of the wound, the parts are liable to suffer contusion, without being reduced, and even to glide between the layers of the abdominal muscles, and become strangulated. When the wound is in the front of the abdomen, pressure made in this unskilful way, may easily make the viscera slip into the sheath of the rectus muscle, and cause the same perilous symptoms, as arise from an incarcerated hernia. (See *Hernia*.)

When the reduction seems complete, the surgeon should assure himself of it, by introducing his finger into the cavity of the abdomen, so as to feel, that the parts are all actually reduced, and suffer no constriction between the edges of the wound and the viscera in the abdomen.

A difficulty of reduction may arise from the protruded intestines being distended with feces, or air. In this circumstance, the contents of the gut may frequently be made to pass, by little and little, into that portion of the intestinal canal, which is within the abdomen. In order to accomplish this purpose, the surgeon must press the contents of the bowel towards the wound, and, if he succeeds in emptying the part, he will commonly experience equal success in his next attempt to replace it in the abdomen.

Sometimes, considerable pieces of intestine are found protruded, through narrow wounds of the abdomen, and their reduction cannot be effected, without doing more violence to the bowel, than its delicate structure would bear. In this case, dilating the wound becomes indispensable. However, frequently, when the reduction seems almost a matter of impossibility, on account of the smallness of the wound, relaxing the abdominal muscles, drawing a little more intestine out of the wound, and gently pressing the contents of the bowel, through the constriction into the abdomen, will render the protruded part sufficiently reducible, without any operation to enlarge the wound.

When such operation is unavoidable, the dilatation should be made in a direction, which will not endanger the epigastric artery, and if possible, in the same line as the muscular fibres.

We are also advised to make the incision upward, rather than downward, when it can be done with equal convenience, because it is supposed the first direction will be followed by less danger of hernia. (*Sabatier, Médecine Opératoire, Tom. 1, p. 220, Edit. 2. Callisen, Syst. Chir. Hod. T. 1, p. 705.*) If, however, the upper angle of the wound correspond to the direction of the suspensory ligament of the liver, writers advise making the dilatation at the lower angle, in order to incur no risk of hemorrhage from the umbilical vein. In general, it is true, this vessel is entirely obliterated in the adult, and turned into a ligamentous substance. Yet, there are some persons, in whom it continues pervious to the navel. Fabricius Hildanus saw a young man die instantaneously in consequence of a narrow stab in the belly between the false ribs and the umbilicus, and, on opening the body, he found that the sudden death had proceeded from a wound of the umbilical vein. It has been feared, also, that cutting the suspensory ligament of the liver, might give rise to such a displacement of that viscus as would interrupt the freedom of respiration, or obstruct the circulation of the blood in the vena cava. But the apprehension appears to be unfounded; for, Riolan found this ligament ruptured and retracted towards the liver in a nimble *Æthiopian* female dancer, whose respiration was not at all affected. (*Sabatier, Méd. Opératoire, T. 1, p. 220, 221. Edit. 2.*)

On account of the possibility of the urachus being pervious, we are likewise recommended to avoid cutting it, if the dilatation can be well made in another direction. (*Callisen, op. cit. p. 705.*)

I believe few surgeons of the present day in England will be inclined to attach any importance to the preceding cautions, respecting the urachus and suspensory ligament of the liver.

It would be unpardonable to make a more extensive incision, than absolutely requisite, as herniæ are very much disposed to occur, wherever the peritoneum has been divided. The operation may be done with a curved bistoury and a director, much in the same way as is done in cases of strangulated ruptures. (See *Hernia*.)

After the battle of Waterloo, we had many cases, in which parts of the bowels and omentum were protruded, and in several, the reduction could not be effected, till the wounds had been enlarged in the way above recommended. So tightly also were the parts girt, that the operation was in several instances far from being easy.

Instead of enlarging wounds of the abdomen, it has been proposed to let out the air from the intestines, by making small punctures with the point of a needle, and thus lessen a volume of the protruded

part sufficiently to render it easily reducible. This suggestion first originated with Ambroise Paré, who declares, that he has several times practised the method with success. Rousset, his cotemporary, also informs us, that the plan was adopted by another surgeon, in an instance, where the epigastric region was wounded, and a large portion of the intestines was protruded and strangulated. Peter Lowe, an English surgeon, likewise assures us, that he has frequently pursued such practice, when other means failed. Garengot, Sharp, and Van Swieten, are all advocates for Paré's proposal; but they recommend employing a round needle, which will merely separate the fibres of the intestinal canal, without cutting them, as a flat, triangular, sharp-edged needle would unavoidably do. These last celebrated writers however, only sanction the practice, when the quantity of protruded intestine is exceedingly great, and when it is so enormously distended with air, that it would be impossible to reduce the part, though the wound were enlarged, and every thing else, likely to promote the reduction, were put in practice. But, as the judicious Sabatier has remarked, the punctures must be entirely useless, if made with a fine needle, since they will be immediately stopped up with the mucous secretion, with which the inside of the bowels is constantly covered; and if the punctures are made with a broad triangular needle, or a very large round one, as Desault and Chopart have advised, they must be highly dangerous, inasmuch as they must be extremely likely to give rise to inflammation, and even to extravasation within the abdomen. (See *Médecine Opératoire*, Tom. 1. p. 10.)

That small punctures in the bowel would not answer the purpose, but be obstructed by the villous, or mucous coat, is a fact, which has been for a long time well known to surgeons. Callisen, amongst others, has particularly noticed it: "*acu puncturæ enim flatibus exitum parare nequeunt, siquidem tunica villosa foraminula obstruit*," &c. (*Syst. Chir. Hod. T. 2. p. 704.*)

It was the circumstance of small punctures being unavailing, that led Desault and Chopart to recommend the use of a large round needle, "*pour que l'ouverture ne soit point bouchée par les mucosités dont les intestines sont enduits*." But, they were also aware of the danger of employing such an instrument, since they give us directions how to proceed, in order to prevent extravasation and inflammation: "*On préviendra l'épanchement des matières stercorales en passant, avant de réduire l'intestin, une anse de fil dans la portion de mésentère qui répond à la piqure pour la fixer contre les bords de la plaie extérieure, et l'on combattra par les remèdes, généraux l'inflammation que cet piqure peut attirer*." (*Traité des Maladies Chirurg. Tom. 2. p. 135.*) One of the most eminent surgeons of Paris

at the present time is an advocate for puncturing the bowel, for which operation he boldly recommends a small hydrocele trocar, (*Richerand, Nosographie Chir. T. 3, p. 336, Edit 4.*)

Mr. Travers, one of the latest and best writers upon this subject, most properly joins in the condemnation of the plan of pricking the protruded bowels. "Blancard and others protested against this practice, on the very sufficient ground of its inefficacy. La Faye very truly says, it is a useless as well as dangerous practice; for the openings, made by a round needle, cannot give issue to the contained air." Mr. Travers then cites two cases, shewing that even small stabs in a bowel will not prevent its becoming distended with air.

"A man was brought to St. Thomas's hospital, on Saturday, the 30th of June last (1811), who had been stabbed in the direction of the epigastric artery, on the left side of the abdomen, by a case knife. He died in eighteen hours, apparently from the sudden and copious hemorrhage, which had taken place within the belly. About half a yard of ileon was protruded. The gut was highly discoloured, and so much distended, notwithstanding it was pierced in three places, that the wound of the integuments required to be freely dilated, before it could be returned. The apertures were in fact obliterated by the mucous coat."

"It appeared upon the trial of Captain Sutherland (Ann. Reg. June 1809) for the murder of his cabin boy, that the intestines had been extensively protruded through a wound near the left groin, and had lain exposed for four or five hours—that the dirk had pierced through one fold of intestine, and entered another—that the wound of the intestine was half an inch long, that the reduction could not be accomplished until the parietal wound was dilated; and that the intestine was then returned, and the integuments sewed up." (*Travers on Injuries of the Intestines*, p. 174, 176.)

I must observe, however, with respect to this last case, that it does not satisfactorily prove what the author intends it to shew, namely, that the bowel was distended with air, though there was a wound in it half an inch long, for, the evidence does not inform us, that the difficulty of reduction was owing to this cause. I have seen a very small portion of omentum protruded through a wound, and baffle all endeavours to reduce it for nearly an hour. The first case, adduced by Mr. Travers, however, is more explicit and interesting; and we are to infer from it, and the observations of Haller, Callisen, &c. that the punctures, made in an intestine, are not closed by mucus, as Sabatier and Desault have asserted, but by the mucous coat itself.

As the above expedient had been re-

commended by writers of some weight, I thought that the subject should not be passed over in silence, and without a caution to the reader, never to put any confidence in the method. The plan does not facilitate the business of the operator; there is not even this solitary reason in favour of the practice; and though it may have answered when large needles were used, and some patients, so treated, may have recovered; yet, every person, who has the least knowledge of the animal economy, will easily comprehend, how even the smallest opening, made in parts, so irritable and prone to inflammation, as the bowels, must be attended with greater danger than would result from enlarging a wound of the skin and muscles. Besides the air may frequently be pressed out of the intestine in a safer way, as I have already described.

A wound of the abdomen, attended with one of the most considerable protrusions of the viscera, that I have ever read of, is recorded by Mr. Hague, surgeon at Ripon: "August 30th 1808 (says this gentleman) I went to Norton Mills, about four miles from hence, to see John Brown, æt. 12 years, who had received a wound in the abdomen by a wool shears. On my arrival, which was little more than an hour after the accident, I found the poor lad in a very distressing situation; the *great arch of the stomach*, and the *whole of the intestinal canal*, (duodenum excepted) contained within the abdomen, having protruded through the wound. The incision was on the left side of the body, commencing at about two inches below the *scrobiculus cordis*, and extending in a straight line near four inches in length, distant from the navel two inches, and he was quite sensible, and had vomited so as to empty the stomach; very little blood was lost. I immediately proceeded very carefully to examine the protruded viscera, none of which were wounded, and reduced them as quickly as possible, beginning with the stomach, and following the regular course of the intestines, in the latter portion of which, I distinctly felt feces, of rather firm consistence. He complained of some pain, during the reduction, though not much, and expressed great relief, when the parts were completely returned. I now desired an assistant to lay the palm of his hand over the wound, and make some pressure upon it; for, I found, that, without this, the parts would soon have protruded again by the action of respiration, which was oppressed and laborious. I brought the sides of the wound together by five sutures, beginning from above downwards, and passed the needle on each side, quite through the integuments with the peritoneum, &c. The wound was also dressed with adhesive plaster, and covered with a bandage." (Vide *Edinburgh Medical and Surgical Journal*, Vol. 5, p. 129, &c.)

This case is really an interesting one; for, notwithstanding so unlimited a protrusion of the viscera, and the parts had been left unreduced for more than an hour, a recovery ensued, under the judicious employment of bleeding, purging, anodynes, &c.

In la Caserne de St. Elizabeth, at Brussels, after the battle of Waterloo, the number of protrusions of the viscera, which fell under my notice, were much more considerable, than what I previously had any idea of ever meeting with. I well remember in my own part of the hospital, two protrusions of a large portion of the stomach; three of the bladder; and ten or twelve of the mesentery, omentum, or intestines.

When the protruded intestine is wounded, the opening is to be closed with a particular suture, before the part is returned into the abdomen. Of this subject, when we speak of wounds of the intestines.

Some of the exposed intestine may have mortified, before the arrival of surgical assistance. This event is exceedingly rare in cases of wounds, but, is not uncommon in those of strangulated herniæ. The treatment is explained in the article *Hernia*.

When the protruded intestine is in a state of inflammation, its immediate reduction is, beyond all dispute, the means most likely to set every thing right. Even when the inflammation has risen to a vehement pitch, a timely reduction of the displaced part, and the employment of antiphlogistic means will often prevent gangrenous mischief. The dull, brown, dark red colour of the intestine may induce the practitioner to suppose, either that the part is already mortified, or must inevitably become so, and, consequently, he may delay returning it into its natural situation. But, notwithstanding this suspicious colour of the intestine, its firmness will evince, that it is not in a state of gangrene. The ultimate recovery of a portion of intestine, so circumstanced, is always a matter of uncertainty; but, the propriety of speedily replacing the part in its natural situation is a thing most certain. "*Partes egressæ sanæ (observes Callisen) citissime sunt reponendæ, neque obstat mutatio coloris nativi in rubrum subfuscum.*" (*Syst. Chir. Hod. T. 1, p. 705, Edit. 1798.*) In case the bowel should mortify after being reduced, all hopes of the preservation of life are not to be abandoned; as we have noticed in the subject of hernia, where many things necessary to be known concerning the mode of reducing protruded omentum, will also be found.

When a piece of intestine cannot be reduced, granulations and new skin may grow over it, as the experience of Callisen confirms. (*Op. cit. p. 706.*)

The protruded viscera having been reduced, the next object is to retain them in

the abdomen, until the wound is completely healed. When the wound is small, this is a matter of no difficulty; in this instance, it is enough to put the patient in such a position, as shall relax the fibres of the wounded muscles, while the edges of the wound are maintained in contact with sticking-plaster, and supported, in this way, by a compress and bandage. Costiveness is to be removed by the mildest purgatives, such as the soda phosphorata and oleum ricini, or by laxative glysters, which are still preferable. But, in cases of extensive wounds, even when the treatment is conducted with all possible judgment, it is occasionally difficult, and even impossible, to hinder the protrusion of the bowels by common dressings, and a bandage. In this circumstance the edges of the wound must be sewed together by a particular suture, named *Gastrophe*. (See this article). It is proper to remark, however, that, in modern times, this suture is very rarely employed, in comparison with what it was formerly, and, in the description of *gastrophe*, some remarks are offered, for the purpose of proving, that the generality of wounds of the abdomen do not require any suture whatsoever.

When the omentum protrudes at a penetrating wound, and is strangulated by the narrowness of the opening, it soon contracts adhesions to it, if not speedily reduced. Should such connexion be already formed, when the surgeon is first consulted, we are advised to cut off the portion, which exceeds the level of the integuments, and to leave the rest in the wound. The latter will block up the opening, and have the good effect of preventing the occurrence of hernia. (*Richerand, Nosographie Chirurgicale, Tom. 3, p. 339, Edit. 4.*) When the protruded omentum is sound and free from adhesions, it ought to be reduced without delay. But, when the protrusion is large, and there is reason to fear, from the vomiting and the pains shooting from the wound to the epigastric region, that the stomach is dragged, the displaced part must be made free, and, if sound, reduced. Should it be in a mortified state, however, the dead part must be previously cut away, and any vessels, which bleed, tied separately with a piece of fine thread, or silk, both ends of which may either be cut off close to the knot, and the part then reduced; or one end may be left out of the wound, and the other cut away. Practitioners, who apprehend ill effects from leaving within the abdomen so small a particle of extraneous matter, as the little knot of fine thread, will prefer the last method, and withdraw the ligature altogether as soon as it becomes loose.

EXTRAVASATION IN THE ABDOMEN.

Wounds of the abdomen may be com-

plicated with extravasations of blood, chyle, excrement, bile, or urine. None of these complications, however, are half so frequent, as an unreflecting and inexperienced practitioner might apprehend. The employment of the phrase *cavity of the abdomen* has paved the way to much erroneous supposition upon this subject, and has induced many absurd notions, which even the sensible observations, long ago published by Petit (*le fils*), have scarcely yet dispelled.

As a modern writer has observed: "there is not truly any cavity in the human body, but, all the hollow bowels are filled with their contents, all the cavities filled with their hollow bowels, and the whole is equally and fairly pressed. Thus, in the abdomen, all the viscera are moved by the diaphragm and the abdominal muscles upwards and downwards, with an equable continual pressure, which has no interval; and one would be apt to add, the intestines have no repose, being kept thus in continual motion; but, though the action of the diaphragm, and the reaction of the abdominal muscles are alternate, the pressure is continual; the motion, which it produces, (they produce) is like that which the bowels have, when we move forwards in walking, having a motion, with respect to space, but none with regard to each other, or to the part of the belly, which covers them; the whole mass of the bowels is alternately pressed, to use a coarse illustration, as if betwixt two broad boards, which keep each turn or intestine in its right place, while the whole mass is regularly moved. When the bowels are forced down by the diaphragm, the abdominal muscles recede: when the bowels are pushed back again, it is the reaction of the abdominal muscles, that forces them back and follows them; there is never an instant of interruption of this pressure, never a moment, in which the bowels do not press against the peritoneum; nor is there the smallest reason to doubt, that the same points in each are continually opposed. We see, that the intestines do not move, or, at least, do not need to move in performing their functions; for, in hernia, where large turns of intestines are cut off by gangrene, the remaining part of the same intestines is closely fixed to the groin, and yet the bowels are easy, and their functions regular. We find the bowels regular, when they lie out of the belly, in hernia, as when a certain turn of intestine lies in the scrotum, or thigh, or, in a hernia of the navel; and where yet they are so absolutely fixed, that the piece of intestine is marked by the straitness of the rings. We find a person, after a wound of the intestine, having free stools for many days; and what is it, that prevents the feces from escaping, but merely

this regular and universal pressure? We find a person, on the fourth or fifth day, with feces coming from the wound! a proof, surely, that the wound of the intestine is still opposite, or nearly opposite, to the external wound. We find the same patient recovering without one bad sign! What better proof than this could we desire, that none of the feces have exuded into the abdomen?

"If in a wound of the stomach, the food could get easily out by that wound, the stomach would unload itself that way, there would be no vomiting, the patient must die; but, so regular and continual is this pressure, that the instant a man is wounded in the stomach, he vomits, he continues vomiting for many days, while not one particle escapes into the cavity of the abdomen. The outward wound is commonly opposite to that of the stomach, and, by that passage, some part of the food comes out; but when any accident removes the inward wound of the stomach from the outward wound, the abdominal muscles press upon the stomach, and follow it so closely, that if there be not a mere laceration extremely wide, this pressure closes the hole, keeps the food in, enables the patient to vomit, and not a particle, even of jellies, or soups, is ever lost, or goes out into the cavity of the belly.

"How (proceeds Mr. J. Bell) without this universal and continual pressure, could the viscera be supported? Could its ligaments, as we call them, support the weight of the liver? Or, what could support the weight of the stomach when filled? Could the mesentery, or omentum, support the intestines; or could its own ligaments, as we still name them, support the womb? How, without this uniform pressure, could these viscera fail to give way and burst? How could the circulation of the abdomen, go on? How could the liver and spleen, so turgid as they are with blood, fail to burst? Or what possibly could support the loose veins and arteries of the abdomen, since many of them, e. g. the splenic vein, is, (are) two feet in length, is (are) of the diameter of the thumb, and has (have) no other, than the common pellucid and delicate coats of the veins? How could the viscera of the abdomen bear shocks and falls, if not supported by the universal pressure of surrounding parts? In short, the accident of hernia being forced out by any blow upon the belly, or by any sudden strain, explains to us how perfectly full the abdomen is, and how ill it is able to bear any pressure, even from its own muscles, without some point yielding, and some one of its bowels being thrown out. And the sickness and faintness, which immediately follow the drawing off of the waters of a dropsy, explain to us, what are the consequences of such pressure being

even for a moment relaxed. But, perhaps, one of the strongest proofs is this, that the principle must be acknowledged, in order to explain what happens daily in wounds; for, though in theory we should be inclined to make this distinction, that the hernia, or abscess of the intestines, will adhere and be safe, but, that wounded intestines, not having time to adhere, will become flaccid, as we see them do in dissections, and so, falling away from the external wound, will pour out their feces into the abdomen, and prove fatal; though we should settle this, as a fair and good distinction in theory, we find, that it will never answer in practice. Soldiers recover daily from the most desperate wounds; and the most likely reasons, that we can assign for it, are, the fulness of the abdomen, the universal, equable, and gentle pressure; and the active disposition of the peritoneum, ready to inflame with the slightest touch. The wounded intestine is, by the universal pressure, kept close to the external wound, and the peritoneum and the intestine are equally inclined to adhere. In a few hours, that adhesion is begun, which is to save the patient's life, and the lips of the wounded intestine are glued to the lips of the external wound. Thus, is the side of the intestine united to the inner surface of the abdomen; and, though the gut casts out its feces, while the wound is open; though it often casts them out more freely, while the first inflammation lasts; yet, the feces resume their regular course, whenever the wound is disposed to close." (*John Bell's Discourses on Wounds*, p. 323, 327, edit. 3.)

The foregoing extract, though drawn up in the most careless style, contains such observations, as are well calculated to make the reader understand, that the abdomen is in reality not a cavity, but a compact mass of containing and contained parts; that the close manner, in which the various surfaces are constantly in contact, must powerfully oppose extravasations; and that, in fact, it often entirely prevents them. The passage cited impresses us with the utility of that quick propensity to the adhesive inflammation, which prevails throughout every peritoneal surface, and which not only often has the effect of permanently hindering effusion of the contents of the viscera, by agglutinating the parts together, but which, even when an extravasation has happened, beneficially confines the effused fluid in one mass, and surrounds it with such adhesions of the parts to each other, as are rapid in their formation, and effectual for the purposes of limiting the extent of the effusion, and preventing the irritation of the extravasated matter from affecting the rest of the abdomen.

It is to M. Petit that we are indebted for the introduction of more correct modes of thinking upon the foregoing subject, and, as his valuable observations in the *Mem. de l'Acad. de Chirurgie*, are highly interesting, they have been introduced into this Dictionary, in the article, *Extravasation*, to which, for the present, I shall be content with referring.

But, notwithstanding the influence of the reciprocal pressure of the containing and contained parts against each other, and the useful effect of the quickly arising adhesive inflammation, in all penetrating wounds of the belly, complicated with the injuries of the viscera, we are not to suppose, that extravasation never happens; but, only that it is much less frequent than has been commonly supposed. Mr. Travers, with much laudable industry, has endeavoured to trace more minutely, than any preceding writer, the particular circumstances, under which effusions in the abdomen are likely or unlikely to happen. "It being admitted (says he) that there are cases, in which effusion does take place, it is easy to conceive circumstances, which must considerably influence this event. If, for example, the stomach and bowels be in a state of emptiness, the nausea, which follows the injury, will maintain that state. If the extent of the wound be considerable, the matter will more readily pass through the wound, than along the canal. A wound of the same dimensions in the small and the large intestines, will more readily evacuate the former, than the latter, because it bears a larger proportion to the calibre. Incised and punctured wounds admit of the adhesion of the cut edges, or the eversion of the internal coat of the gut, so as to be in many instances actually obliterated; whereas, lacerated, or ulcerated openings, do not admit of these salutary processes. Again, in a transverse section of the bowel, contraction of the circular fibre closes the wound, whereas in a longitudinal section, the contraction of this fibre enlarges it. Such (says Mr. Travers) are the circumstances, which combined, in a greater or less degree, increase or diminish the tendency to effusion." (*On Injuries of Intestines, &c.* p. 13—14.)

After the details of some experiments and cases, the preceding author makes among other conclusions, the following:

1. That effusion is not an ordinary consequence of penetrating wounds.

2. That, if the gut be full and the wound extensive, the surrounding pressure is overcome, by the natural action of the bowel tending to the expulsion of its contents.

3. That, if food has not recently been taken, and the wound amounts to a division of the gut, or nearly so, the eversion and contraction of the orifice of the tube, prevent effusion.

4. That, if the canal be empty at the time of the wound, no subsequent state of the bowel will cause effusion, because the supervening inflammation agglutinates the surrounding surfaces, and forms a circumscribed sac; nor can effusion take place from a bowel at the moment full, provided it retains a certain portion of its cylinder entire, the wound not amounting nearly to a semidivision of the tube, for then the eversion and contraction are too partial to prevent an extravasation.

5. That, when however air has escaped from the bowel, or blood has been extravasated in quantity within the abdomen at the time of the injury, the resistance, opposed to effusion, will be less effectual, although the parietal pressure is the same, as such fluids will yield more readily, than the solids naturally in contact. P. 25—26, 100.

6. That, though extravasation is not common in penetrating wounds, it follows more generally in cases, where the bowel is ruptured by blows, or falls upon the belly, while the integuments continue unwounded. P. 36.

7. That when the bowels are perforated by ulceration, there is more tendency to effusion, than in cases of wounds. P. 38, &c.

Mr. Travers attempts to explain the reason of the greater tendency to effusion, in cases of intestine burst by violence, and in those of ulceration, "by the difference in the nature of the injury, which the bowel sustains, when perforated by a sword or bullet, as in the one case, or burst or ulcerated in the other. A rupture by concussion could only take place under a distended state of the bowel, a condition most favourable to effusion, and from the texture of the part, a rupture, so produced, would seldom be of limited extent. The process of ulceration, by which an aperture is formed, commences in the *internal* coat of the bowel, which has always incurred a more extensive lesion, than the peritoneal covering. The puncture, or cut, is merely a solution of continuity in a point, or line; the ulcerated wound is an actual loss of substance. The consequence of this difference is, that, while the former, if small, is glued up by the effusion from the cut vessels, or, if large, is nearly obliterated, by the full eversion of the villous coat, the latter is a permanent orifice." P. 46.

How much Mr. Travers and Mr. John Bell differ in opinion, upon these latter points, will appear from the following passage: after adverting to the adhesion, which takes place between the viscera and the peritoneum, under a variety of circumstances attending disease, Mr. John Bell observes: "this it is, which makes the chief difference, in point of danger, betwixt an ulcerated and a wounded intes-

time ; for, in a wound, there is, as we should suppose, no time for adhesion, nothing to keep the parts in contact, no cause, by which the adhesion might be produced. But, in an ulcer, there is a slow disease, tedious inflammation, adhesion first, and abscess, and bursting afterwards; sometimes a fistula remains discharging feces, and sometimes there is a perfect cure. If a nutshell, a large coin, a bone, or any dangerous thing be swallowed, it stops in the stomach, causing swelling and dreadful pain ; at last, a hard firm tumour appears, and then it suppurates, bursts, the bowel opens, the food is discharged at every meal, till the fistula gradually lessens, and heals at last. But, where the stomach is cut with a broad wound of a sabre, the blood from the wounded epiploic vessels, or the food itself, too often pours out into the abdomen, and the patient dies," &c. (*Discourses on Wounds*, p. 321, edit. 3.) The author afterwards proceeds to explain, how the compact state of the containing and contained parts, and the incessant and equable pressure, which the viscera sustain, frequently hinder effusion in cases of penetrating wounds.

Which of these gentlemen is most correct on the subject, I cannot pretend to say. Mr. Travers has certainly adduced a few cases, in favour of his own statement. Whether they are deviations from what is most common, can only be decided by a comparative examination of a greater number of facts. When the intestines ulcerate, and thus rid themselves of foreign bodies, the general tenor of the cases on record undoubtedly affords us little reason to be apprehensive of extravasation. Yet, with respect to ulceration of the intestines from other causes, circumstances may be very different.

Mr. Travers's account of the subject has very lately received some confirmation from an interesting case, published by Dr. John Crampton, assistant physician to Steevens' Hospital, Dublin. It is an instance of rupture of the stomach, and fatal effusion of its contents into the cavity of the abdomen. The patient was a young lady, aged 29. She was suddenly taken ill with spasm in her stomach, and other severe symptoms, and died in about twelve hours. "On opening the abdomen, the stomach was observed to be pale, flaccid, and empty. Its contents, amongst which were recognized oatmeal and castor oil, had escaped into the cavity of the abdomen, through a round aperture situated on its anterior surface, at the union of the cardiac and pyloric portions. This perforation of the stomach was perfectly circular, about the size of a pea, and appeared to be the result of an ulcer on the mucous surface, which had gradually penetrated the other coats. This ulcer was

hollow and circular, nearly the size of a shilling, and had the appearance, as if it had been made with caustic, with the orifice in its centre." (*J. Crampton in Med. and Chir. Trans. Vol. 8, p. 230.*) To the preceding, Mr. Travers has annexed some additional facts: one is an example of a rapidly fatal effusion of the intestinal contents, through an ulcerated opening about a finger's breadth below the pylorus. The foramen had a peritoneal margin, and proved to be the centre of an irregular superficial ulcer of the mucous coat. Another case is that of a similar ulceration of the small intestines, and fatal extravasation of their contents. In another example, a circular aperture of the peritoneum, large enough to admit a crow's quill, was found after death at the junction of the duodenum and stomach. It also was the centre of an ulcer, that had destroyed the villous and muscular coats of the bowel to the extent of half an inch. For many other ingenious observations, I must refer the reader to Mr. Travers's paper, who concludes with remarking, that the chief diagnostic symptoms of these hopeless cases appear to be :

1. Sudden, most acute, and unremitting pain, radiating from the scrobiculus cordis, or the navel, to the circumference of the trunk, and even to the limbs. A peculiar pain, the intensity of which, like that of parturition, absorbs the whole mind of the patient, who, within an hour from the enjoyment of perfect health, expresses his serious and decided conviction, that if the pain be not speedily alleviated, he must die.

2. Coeval with the attack of pain, remarkable rigidity and hardness of the belly, from a fixed and spastic contraction of the abdominal muscles.

3. A natural pulse for some hours, until the symptoms are merged in those of acute peritonitis, and its fatal termination in the adhesive stage. (*Travers, in Med. and Chir. Trans. Vol. 8, p. 231, et seq.*)

Blood is more frequently extravasated in the abdomen, than any other fluid. Extravasations of this kind, however, do not invariably happen, whenever vessels of not a very considerable size are wounded. The compact state of the abdominal viscera, in regard to each other, and their action on each other, oppose this effect. The action alluded to, which depends on the abdominal muscles and diaphragm, is rendered very manifest by what happens, in consequence of operations for hernie attended with alteration of the intestines, or omentum. If these viscera should burst, or suppurate, after being reduced, the matter which escapes from them, or the pus, which they secrete, is not lost in the abdomen ; but is propelled towards the wound of the skin, and there makes its exit. The intestinal

matter, effused from a mortified bowel, has been known to remain lodged the whole interval, between one time of dressing the wound and another, in consequence of the surgeon stopping up the external wound with a large tent. When the abovementioned action or pressure of the muscles, is not sufficient to keep the blood from making its escape from the vessels, still it may hinder it from becoming diffused among the convolutions of the viscera, and thus the extravasation is confined in one mass. The blood, effused and accumulated in this way, is commonly lodged at the inferior and anterior part of the abdomen, above the lateral part of the pubes, and by the side of one of the recti muscles. The weight of the blood may propel it into this situation, or perhaps, there may be less resistance in this direction, than in another. In opening the bodies of persons, who have died with such extravasations, things may put on a different aspect, and the blood seem to be promiscuously extravasated over every part of the abdomen. But, when such bodies are examined with care, it will be found, that the blood does not insinuate itself among the viscera, till the moment when the abdomen is opened, and the mass previously lies in a kind of pouch. This pouch is frequently circumscribed, and bounded by thick membranes, especially when the extravasation has been of some standing. (*Sabatier Médecine Opératoire, Tom. 1, p. 28—30.*)

It is of the highest consequence to a practical surgeon to remember well, that all the parts contained in the abdomen are closely in contact with each other, and with the inner surface of the peritoneum. This is one grand reason, why extravasations are seldom so extensively diffused as one might imagine; but, commonly lie in one mass, as Petit, Sabatier, and all the best moderns have noticed. The pressure of the elastic bowels, of the diaphragm, and abdominal muscles, not only frequently presents an obstacle to the diffusion of extravasated matter, but often serves to propel it towards the mouth of the wound. The records of surgery make mention of numerous instances, in which persons have been stabbed through the body, without any fatal consequences, and sometimes without the symptoms being even severe. In Mr. Travers's publication many cases, exemplifying this observation, are quoted from a variety of sources; Fab. Hildan. *Obs. Chirurg. Cent. 5. Obs. 74. Œuvres de Paré, liv. 10. Chap. 35. Wiseman's Surgery, p. 371. La Motte's Traité Complet de Chirurgie; &c. &c.* In such cases the bowels have been supposed to have eluded the point of the weapon, and this may perhaps in a few instances have been actually the fact; but, in almost all such examples, there can be no doubt, that the bowels

have been punctured, and an extravasation of intestinal matter has been prevented by the opposite pressure of the adjacent viscera. Such resistance and pressure may, also, have occasionally obliged intestinal matter, or blood, actually extravasated, to pass through the wound of the bowel into its cavity, and thus be speedily removed. Certain it is, such copious evacuations of blood *per anum* have followed stabs of the abdomen, as could hardly proceed from the arteries of the intestines. This way of getting rid of an extravasation must be rare, however, compared with that by absorption.

The pouch, or cyst, including extravasated blood, or matter, as mentioned by Sabatier, is formed by the same process, which circumscribes the matter of abscesses. (See *Suppuration.*) It is, in short, the adhesive inflammation. All the surfaces in contact with each other, and surrounding the extravasation, and track of the wound, generally soon become so intimately connected together by the adhesive inflammation, that the place in which the extravasation is lodged, is a cavity entirely destitute of all communication with the cavity of the peritoneum. The track of the wound leads to the seat of the effused fluid, but has no distinct opening into the general cavity of the abdomen. The rapidity with which the above adhesions form is often very great, almost incredible.

It should be known, however, that extravasations are occasionally diffused in various degrees among the viscera, owing to the patient being subjected to a great deal of motion, or his having violent spasmodic contractions of the intestines, arising from the irritation of the extravasated matter. Urine and bile are more frequently dispersed to a great extent among the abdominal viscera, than blood. The latter fluid, indeed, must often coagulate; a circumstance that must tend both to stop further hemorrhage, and confine the extravasation in one mass.

SYMPTOMS AND TREATMENT OF EXTRAVASATIONS IN THE ABDOMEN.

1. Blood.

Wounds of the spleen, and of such veins and arteries, as are above a certain size, almost always prove fatal from internal hemorrhage. The blood generally makes its way downwards, and accumulates at the inferior part of the abdomen, unless the existence of adhesions happen to oppose the descent of the fluid to the most depending situation. The belly swells, and the fluctuation of a fluid is perceptible through the anterior part of the abdominal parietes. The patient grows pale, loses his strength, is affected with syncope, and his pulse becomes weaker and weaker. In short, the

symptoms, usually attendant on hemorrhage, are observable. The viscera and vessels in the abdomen being continually compressed on all sides, by the surrounding parts, the blood cannot be effused, without overcoming a certain degree of resistance; and unless a vessel of the first magnitude, like the aorta, the vena cava, or one of their principal branches, has been wounded, the blood escapes from the vessel slowly, and several days elapse, before any considerable quantity has accumulated in the lesser cavity of the pelvis.

In these cases of extravasated blood, the symptoms which, perhaps, had disappeared, under the employment of bleeding and anodyne medicines, now come on again. A soft, fluctuating tumour may be felt at the lower part of the abdomen; sometimes on the right side; sometimes on the left; occasionally, on both sides. The pressure, made by the effused blood on the urinary bladder, excites distressing inclinations to make water; while the pressure, which the sigmoid flexure of the colon suffers, is the cause of obstinate constipation. In the mean time, the quantity of extravasated blood increasing, irritation and inflammation of the peritoneum are induced. The pulse grows weaker; debility ensues; the countenance is moistened with cold perspirations; and, unless instigated by all the antecedent circumstances, the surgeon practises an incision for the discharge of the fluid, the patient falls a victim to the accident.

In the year 1733, Vacher, principal surgeon of the military hospital at Besancon, successfully adopted this mode of treatment, as I have more particularly noticed in the article *Extravasation*. Petit (the son) afterwards tried the same plan, though it did not answer, (as is alleged) in consequence of the inflammation having advanced too far, before the operation was performed. Long before the time of Vacher and Petit, a successful instance of similar practice had been recorded by Cabrole, in a work, which this author published, under the title of *Αλφαβητον ανατομικον*, id est, *Anatomes elenchus accuratissimus, omnes humani corporis partes eâ quâ solent secari methodo, delineans. Accessere osteologia, observationesque Medicis ac Chirurgis peritiles*. Genève 1604. Hence, as Sabatier has remarked, the method pursued by Vacher was not so new as Petit imagined. (*Médecine Opératoire*, Tom. 1, p. 32.)

Indeed, when the symptoms leave no doubt of there being a large quantity of blood extravasated in the abdomen; when the patient's complaints are of a very serious nature, and are evidently owing to the irritation and pressure of the blood on the surrounding viscera; and when a local swelling denotes the seat of the extravasation, there cannot be two opinions about

the propriety of making an incision for its evacuation.

Surgeons, however, should recollect, that a small extravasation of blood may exist, without producing any considerable irritation, provided no opening be made into the cyst, with which it becomes surrounded. On the contrary, when such cyst is opened, the air then having free access to the blood contained there, that part of the fluid, which cannot be discharged, is apt to putrify, and become so irritating, as to excite inflammation of the surrounding parts. — Even though there may be an evident extravasation of blood, the bad symptoms are also sometimes entirely owing to the injury done to the parts within the abdomen, and neither to the pressure, nor the irritation of the effused blood.

But, sometimes, as we have already noticed, the accumulated blood at first, neither irritates the adjacent parts by its quantity nor quality. An inflammation, however, of the parts surrounding the extravasation, at length takes place. The tension, irritation, and pain, which, in the first instance, arose from the wound itself, and subsided, seem now to be renewed. When the extravasation is at the lower and anterior part of the abdomen, the patient experiences pain about the hypogastric region. He is also constipated, and, as he suffers great irritation of the bladder, he feels frequent propensities to make water, but cannot relieve himself. At last, a tumour makes its appearance, attended with a fluctuation more or less distinct.

In this instance, it seems proper to give vent to the accumulated blood. If this fluid should be found coagulated, injections of warm water would facilitate its discharge. (*Sabatier Médecine Opératoire*, Tom. 1.)

2. Chyle and Feces.

These are not so easily extravasated in the abdomen as blood, because they do not require so much resistance, on the outside of the stomach and intestines, to make them continue their natural route through the alimentary canal, as blood requires to keep it in the vessels. Extravasations of this kind, however, sometimes happen, when the wound is large and the bowel distended at the moment of the injury, or when, as Mr. Travers has likewise explained, air is extravasated, or blood effused in the abdomen; these fluids being incapable of making effectual resistance to the escape of the intestinal matter. (See an *Enquiry into the Process of Nature in repairing Injuries of the Intestines*, &c. p. 26.) Nothing is a better proof of the difficulty with which chyle and feces are extravasated, than the operation of an emetic, when the stomach is wounded and full of aliment. In this instance, if the resistance to the extravasa-

tion of the contents of the stomach were not considerable, they would be effused in the abdomen, instead of being vomited up. A peculiarity in wounds of the stomach and intestines is, that the opening, which allows their contents to escape, may also allow them to return into the wounded viscus.

Extravasation of intestinal matter in the abdomen is attended with a severe train of febrile symptoms; dryness of the mouth, tongue, and fauces; considerable pain and swelling of the belly; convulsive startings; and hiccough and vomiting, with which the patients are generally attacked the day after the receipt of the wound. (*Sabatier de la Médecine Opératoire, Tom. 1, p. 34.*)

In these cases, general means are the only ones, which can be employed; venesection, fomentations, low diet, perfect rest, anodynes, &c. All solid food must be most strictly prohibited. The close state of the viscera may also be increased by applying a bandage round the body.

If the symptoms are not speedily assuaged, the abdominal viscera become affected with general inflammation, and gangrene, and the patients die in the course of a few days.

3. Bile.

Bile, on account of its great fluidity, is more easily extravasated extensively in the abdomen, than either blood, or the contents of the stomach and intestines. Besides, the gall bladder has the power of contracting itself so completely, as to expel the whole of its contents. Notwithstanding these circumstances, however, extravasations of this kind are exceedingly uncommon, doubtless, on account of the small size of the gall bladder, and its deep guarded situation, between the concave surface of the liver, and upper part of the transverse arch of the colon.

Sabatier informs us, that he has only been able to find one example on record. This case, after having been communicated to the Royal Society of London, by Dr. Steward (No. 414, pag. 341. Abridgm. Vol. 7, pag. 571-572), was inserted, as an extract, in the third volume of the *Edinburgh Essays*, and also in the third volume of *Van Swieten's Commentaries on the Aphorisms of Boerhaave*, (transl. p. 65, edit. 1754). An officer received a wound, penetrating the cavity of the abdomen, and entering the fundus of the gall bladder, without doing any material injury to the adjacent parts. The abdomen was immediately distended, as if the patient had been afflicted with an ascites, or tympanitis; nor did the swelling either increase, or diminish, till the patient's death, which happened a week after the infliction of the wound.

There was no rumbling noise in the abdomen, though it was exceedingly tense. There were no stools, and very little urine was discharged, notwithstanding purgatives, and glysters, and a good deal of liquid nourishment, were given. The patient never had one instant of sound sleep, but was always restless, though anodynes were exhibited. There was no appearance of fever, and the pulse was always natural till the last day of the patient's life, when it became intermittent. The intestines were found, after death, very much distended, the gall bladder quite empty, and a large quantity of bile extravasated in the abdomen.

Sabatier met with an opportunity of observing the symptoms of an extravasation of bile, in consequence of a wound of the gall bladder. The patient's abdomen swelled very quickly; his respiration became difficult, and he soon afterwards complained of tension, and pain in the right hypochondrium. His pulse was small, frequent, and contracted; his extremities were cold, and his countenance very pale. The bleedings, which were practised the first day, gave him a little relief; but the tension of the abdomen, and the difficulty of breathing, still continued. A third bleeding threw the patient into the lowest state of weakness, and he vomited up a greenish matter. On the third day, the lower part of the belly was observed to be more prominent, and there was no doubt of an extravasation. M. Sabatier introduced a trocar, and gave vent to a green blackish fluid, which had no smell, and was pure bile, that had escaped from the wound of the gall bladder. After the operation, the patient grew weaker and weaker, and died in a few hours. On opening the body, a large quantity of yellow bile was found between the peritoneum and intestines; but, it had not insinuated itself among the convolutions of the viscera. A thick gluten connected the bowels together, and they were prodigiously distended. The gall bladder was shrivelled, and almost empty. Towards its fundus, there was a wound, about a line and a half long, corresponding to a similar wound in the peritoneum. The wound, which had occurred at the middle and lower part of the right hypochondrium, between the third and fourth false ribs, had glided from behind forward, and from above downward, between the cartilages of the ribs, until it reached the fundus of the gall bladder.

Sabatier takes notice, that the symptoms of the two cases, which have just now been related, were very similar. Both the patients were affected with an exceedingly tense swelling of the belly unattended with pain, or borborygmus, and they were both obstinately constipated. Their pulse was extremely weak the latter days of their in-

disposition, and they were afflicted with hiccough, nausea, and vomiting.

M. Sabatier seems to think one thing certain, viz. that wounds of the gall bladder attended with effusion of bile, are absolutely mortal, and that no operation can be of any avail. (*Médecine Opératoire*, Tom. 1, p. 34—37.)

We are however to infer the contrary from the extraordinary case lately published by Mr. Fryer, of Stamford. A boy, about thirteen years old, received a violent blow from one of the shafts of a cart, on the region of the liver. The injury was succeeded by pain, frequent vomiting of bilious matter, great sinking, coldness of the extremities, and a weak, small, fluttering pulse. The belly was fomented, and purging clysters thrown up. On the third day, symptoms of inflammation began, attended with considerable pain about the liver, great tension and soreness of the abdomen, and frequent vomiting. The pulse was quick, small, and weak; the skin hot and dry; the tongue much furred; the urine high-coloured; and there was some difficulty of breathing; and great thirst. Eight ounces of blood were taken away, the fomentations continued, and a few grains of calomel were directed to be given every four hours until the bowels were properly opened. Afterwards the effervescing mixture, with ten drops of laudanum, was exhibited every four hours.

On the following day, the patient had had some motions, and was much better; but, as his sickness continued, he was ordered a grain of opium every four hours. About a week afterwards, he complained of a great increase of pain, which was somewhat relieved by a blister. He was now completely jaundiced, and his stools were white, but the tension, pain, and sickness were abated.

Two days afterwards, a fluctuation was perceived in the abdomen, which in another week became considerably distended with fluid. The patient now did not complain of much pain; but appeared to be sinking fast: A puncture was made in the swelling, and thirteen pints of what appeared to be pure bile were evacuated. The bowels then soon became regular, and the appetite good. In twelve days, the operation was repeated, and fifteen pints of the same bilious fluid were drawn off. Nine days afterwards, another puncture was made, and thirteen pints more let out; and six were discharged in another fortnight. From this period the boy went on well, and perfectly recovered under the use of light tonic medicines. (See *Medico-Chirurgical Transactions*, Vol. 4, p. 330.)

A previous accidental adhesion of the gall bladder to the peritoneum might also certainly prevent the extravasation of bile, and its dangerous effects. (*Callisen, Syst. Chir. Hodierna*, T. 1, p. 718.)

4. Urine.

Urine being of a very fluid nature may, like the bile, be easily extravasated in the abdomen, when the bladder is wounded at any part, which is connected with the peritoneum. If the urine, in this kind of case, be not drawn off with a catheter, so as to prevent it from issuing by the wound of the bladder, the patient soon perishes. There are many instances recorded of the bladder being injured even by gun-shot wounds, which were not mortal. Such wounds, however, might only have injured the sides, or lower part of the bladder. But, in operating for the stone, above the pubes, the bladder has undoubtedly been occasionally cut at the part of the fundus, which is covered with the peritoneum. However, as the accident was known in the first instance, the right treatment was adopted, and such patients have recovered. (*Sabatier, Médecine Opératoire*, Tom. 1, p. 37.)

Wounds of the bladder are particularly characterized by a discharge of bloody urine and difficulty of making water. They must always be regarded as dangerous cases, both on account of the risk of the effusion of so irritating a fluid in the abdomen, and of the chance of extravasation in the cellular membrane. Under proper treatment, however, they often admit of cure. (See *Gun-shot Wounds*.) The effused fluid should, if possible, be discharged by a depending posture, or suitable punctures, or incisions, and its recurrence prevented by the introduction of a catheter, which is to be left in the urethra. The patient must also be allowed little drink. As for the tension and pain of the belly, the common attendants of a wounded bladder, they may be greatly relieved by the use of the warm bath. (*Callisen*, T. 1, p. 719.) Bleeding and other antiphlogistic means are not to be omitted.

WOUNDS OF THE INTESTINES.

The vomiting of blood, or discharge of it by stool, the escape of fetid air, or of intestinal matter, from the mouth of the wound; an empty collapsed state of a portion of bowel, protruded at the opening in the skin, are the common symptoms attending a wound of this kind. When the wound is situated in the protruded portion, it is obvious to the surgeon's eye; but when it affects a part of the intestinal canal within the abdomen, the nature of the case can only be known by a consideration of other symptoms. In addition to such as I have already described, there are some others, which ordinarily accompany wounds of the bowels; as, for instance, oppression about the præcordia, acute or griping pain in the belly, cold sweats, syncope, &c. But unless the wounded intestine be protruded, there is no

practical good in knowing whether the bowel is injured or not, since, if it be in the abdomen, the treatment ought not to be materially different from that of a simple penetrating wound of the belly, unattended with a wound of any of the viscera. Large wounds of the small intestines, particularly, of the duodenum and jejunum, are attended with acute fever, anxiety, paleness of the countenance, syncope, cold perspirations, a small, intermitting, tremulous pulse, and they frequently prove fatal. Injuries of the small intestines are also more often, than those of the large ones, followed by extravasation. A total division of the upper part of the intestinal canal, towards the pylorus, will deprive the body of the nourishment requisite for its support. If the chyle escape from the wound, the patient will die of a slow marasmus; and if it become extravasated, it will be likely to excite such irritation as will prove fatal. The escape of excrement, or of fetid air from the wound, indicates an injury of one of the large intestines. In these cases, the symptoms are generally milder, and the passage of the intestinal contents outward through the wound more easy, on account of the bowel being less moveable. For the same reason, the wounded intestine more readily contracts an adhesion to the adjacent parts. (*Callisen, Syst. Chirurgiæ Hodiernæ, T. 1, p. 717.*)

A wounded intestine is said to present some particular appearances, to which the generality of writers have paid no attention: "If a gut be punctured, the elasticity of the peritoneum, and the contraction of the muscular fibres, open the wound, and the villous, or mucous coat, forms a sort of hernial protrusion, and obliterates the aperture. If an incised wound be made, the edges are drawn asunder and reverted, so that the mucous coat is elevated in the form of a fleshy lip. If the section be transverse, the lip is broad and bulbous, and acquires tumefaction and redness from the contraction of the circular fibres behind it, which produces, relatively to the everted portion, the appearance of a cervix. If the incision is according to the length of the cylinder, the lip is narrow, and the contraction of the adjacent longitudinal, resisting that of the circular fibres, gives the orifice an oval form. This eversion and contraction are produced by that series of motions, which constitutes the peristaltic action of the intestines." (*Travers on Injuries of the Intestines, p. 85.*)

According to this gentleman, some of these appearances were described by Haller, in *Element. Physiol. lib. 24, sect. 2. and Opera Minora, tom. 1, sect. 15.*

Having witnessed the facility, with which considerable injuries of the intestinal tube were repaired, Mr. Travers was desirous

of ascertaining more fully the powers of nature in the process of spontaneous reparation, and of determining, under how great a degree of injury, it would commence, as well as the mode of its accomplishment. For these purposes, he divided the small intestine of several dogs as far as the mesentery. All these animals died, in consequence of the intestinal matter being extravasated, if they had been lately fed, or if they had been fasting in consequence of inflammation, attended with a separation of the ends of the divided bowel, eversion of the mucous coat, and obliteration of the cavity, partly, by this eversion, and partly by a plug of coagulated chyle.

In one particular instance in which Mr. Travers made a division of the bowel, half through its diameter, a sort of pouch was formed round the injured intestine. "A pouch, resembling somewhat the diverticulum in these animals, was formed opposite to the external wound, on the side of the parietes, by the lining peritoneum, on the other side, by the mesentery of the injured intestine, that intestine itself, and an adjacent fold, which had contracted with it a close adhesion. The pouch, thus formed and insulated, included the opposed sections of the gut, and had received its contents, &c. The tube, at the orifices, was narrowed by the half eversion, but offered no impediment to the passage of fluids." (*P. 96.*) Whether, under these circumstances, the functions of the alimentary canal could have been continued, Mr. Travers professes himself incapable of deciding. Among the inferences, which this gentleman has drawn from the experiments, detailed in his publication, the tendency of the two portions of a divided bowel to recede from each other, instead of coalescing to repair the injury, merits notice, in as much as it tends to shew, that the only means of spontaneous reparation consist in the formation of an adventitious canal, by the encircling bowels and their appendages. The everted mucous coat, which is the part opposed to the surrounding peritoneum, is also indisposed to the adhesive inflammation.

When, however, the wound of the intestine is smaller, the obstacles to reparation are not absolutely insurmountable. Here, retraction is prevented, and the processes of eversion and contraction modified by the limited extent of the injury. If, therefore, the adhesive inflammation unite the contiguous surfaces, effusion will be prevented, and the animal escape immediate destruction. But, union can only take place through the medium of the surrounding parts.

According to Mr. Travers, it is the retraction immediately following the wound, that is a chief obstacle to the reparation of the injury; for, if the division be performed

in such a way, as to prevent retraction, the canal will be restored in so short a time, as but slightly to interrupt the digestive function. In confirmation of this state, a ligature was tightly applied round the duodenum of a dog, which became ill, but entirely recovered, and was killed. "A ligature, fastened around the intestine, divides the interior coats of the gut, in this effect resembling the operation of a ligature upon an artery. The peritoneal tunic alone maintains its integrity. The inflammation, which the ligature induces on either side of it, is terminated by the deposition of a coat of lymph, which is exterior to the ligature, and quickly becomes organized. When the ligature, thus enclosed, is liberated by the ulcerative process, it falls of necessity into the canal, and passes off with its contents." (P. 103—104.)

It appears also from Mr. Travers's experiments and observations, that longitudinal wounds of the bowels are more easily repaired than such as are transverse. In a dog, a longitudinal wound, of the extent of an inch and a half, was repaired by the adhesive inflammation. Here the process of eversion is very limited; the aperture bears a smaller proportion to the cylinder of the bowel; and the entire longitudinal fibres resist the action of the circular, which are divided, and can now only slightly lessen the area of the canal. (P. 108).

We come now to the consideration of the treatment, which may be proper in cases of wounds of the intestines; a subject in which much difference of opinion has prevailed; principally, however, concerning the circumstances, in which sutures are necessary, and the most advantageous way of applying them.

When the wounded bowel lies within the cavity of the abdomen, no surgeon of the present day would have the rashness to think of attempting to expose the injured intestine, for the purpose of sewing up the breach of continuity in it. In fact, the surgeon seldom knows at first what has happened; and when the nature of the case is afterwards manifested, by the discharge of blood per anum, an extravasation of intestinal matter, &c. it would be impossible to get at the injured part of the bowel, not only because its exact situation is unknown, but, more particularly, on account of the adhesions, which are always formed with surprising rapidity. But, even if the surgeon knew, to a certainty, in the first instance, that one of the bowels was wounded, and the precise situation of the injury, no suture could be applied, without considerably enlarging the external wound, drawing the wounded intestine out of the cavity of the abdomen, and handling and disturbing all the adjacent viscera. Nothing would be more likely, than such proceedings, to render the accident, which

may originally be curable, unavoidably fatal. I entirely agree upon this point with Mr. John Bell, who says, "When there is a wounded intestine, which we are warned of only by the passing out of the feces, we must not pretend to search for it, nor put in our finger, nor expect to sew it to the wound; but we may trust, that the universal pressure, which prevents great effusion of blood, and collects the blood into one place, that very pressure, which always causes the wounded bowel and no other to protrude, will make the two wounds, the outward wound and the inward wound of the intestine, oppose each other, point to point; and, if all be kept there quiet, though but for one day, so lively is the tendency to inflame, that the adhesion will be begun, which is to save the patient's life." (*Discourses on Wounds*, p. 361, edit. 3.)

When the extravasation, and other symptoms, a few days after the accident, shew the nature of the case, a suture can be of no use whatever, as the adhesive inflammation has already fixed the part in its situation, and the space, in which the extravasation lies, is completely separated from the general cavity of the abdomen, by the surrounding adhesions.

When the bowel is not protruded, and the opening in it is situated closely behind the wound in the peritoneum, a suture is not requisite, for the contents of the gut not passing onward, will be discharged from the outer wound, and not be diffused among the viscera, if care be taken to keep the external wound open. There is no danger of the wounded bowel changing its situation, and becoming distant from the wound in the peritoneum, for the situation which it now occupies is its natural one. Nothing, but violent motion, or exertions, could cause so unfavourable an occurrence, and these should always be avoided. The adhesions which take place in the course of a day or two, at length render it impossible for the bowel to shift its situation.

Things, however, are far different when the wounded part of the bowel happens to be protruded. Here we have the authority of all writers, in sanction of the employment of a suture. No enlargement of the outer wound is requisite to enable the practitioner to adopt such practice; there is no disturbance of the adjacent parts; there is no doubt concerning the actual existence of the injury, no difficulty in immediately finding out its situation.

But, though authors are so generally agreed about the propriety of using a suture, in the case of a wounded and protruded bowel, they differ exceedingly, both as to the right object of the method, and the most advantageous mode of sewing the injured part of the intestine. Some have little apprehension of extravasation, advise

only one stitch to be made, and use the ligature chiefly with a view of confining the injured bowel near the external wound, so that, in the event of an extravasation, the effused matter may find its way outward. Other writers wish to remove the possibility of extravasation, by applying numerous stitches, and attach little importance to the plan of using the ligature principally for the purpose of keeping the intestine near the superficial wound.

When the wound of a bowel is so small, that it is closed by the protrusion of the villous coat, the application of a suture must evidently be altogether needless; and since the ligature would not fail to cause irritation, as an extraneous substance, the employment of it ought unquestionably to be dispensed with.

Supposing, however, the breach in the intestine to be small, but yet sufficient to let the feces escape, what method ought to be adopted? The following practice seems rational. As Mr. Astley Cooper was performing the operation for a strangulated hernia, at Guy's hospital, an aperture, giving issue to the intestinal contents, was discovered in a portion of the sound bowel, just when the part was about to be reduced. The operator, including the aperture in his forceps, caused a fine silk ligature to be carried beneath the point of the instrument, firmly tied upon the gut, and the ends cut off close to the intestine. The part was then replaced, and the patient did well. Mr. Travers, who has related this fact, approves of the plan of cutting away the extremities of the ligature, instead of leaving them hanging out of the external wound. It appears, that, when the first practice is followed, the remnant always makes its way into the intestine, and is discharged with the stools, without any inconvenience. But, when the long ends are drawn through the outer wound, and left in it, they materially retard the process of healing. (See *Travers on Injuries of the Intestines*, &c. p. 112, 113.)

Let us now enquire into what ought to be the conduct of a surgeon, should he be called to a patient, whose bowel is divided through its whole cylinder, and protruded out of the external wound.

Various have been the schemes and proposals, for the treatment of this sort of accident; and since experience has furnished few practitioners with an opportunity of seeing such a case in the human subject, a variety of experiments have been made on animals, in order to determine what treatment would be the most successful. Ramdohr, indeed, is stated by Moebius to have had occasion to try on the human subject, a plan, of which a vast deal has been said and written. He cut off a large part of a mortified intestine, and joined

the two sound ends together, by inserting the upper within the lower one, and fixing them in this position with a suture, the ligature being also employed to keep them at the same time near the external wound. The patient recovered, and the feces continued to pass entirely by the rectum in the natural way. (See *Halleri Disput. Anat. Vol. 6. Obs. Med. Miscellan.* 18.)

About a year after the operation, the patient died, when the anatomical preparation of the parts was sent by Ramdohr to Heister. They were preserved in spirits of wine, and exhibited, according to the latter author, an union of the two ends of the bowel together, and *their consolidation with a part of the abdomen*. Now it has been questioned by a late writer, whether the union here spoken of ever really happened. When the upper end of the bowel is introduced into the lower, the external surface of the former is put in contact with the inner one of the latter; a serous membrane is placed in opposition with a mucous one. These heterogeneous structures, he alleges, are not disposed to unite. The mucous membrane, when inflamed, more readily secretes a kind of mucus, which would be an invincible obstacle to adhesion. He thinks it therefore more than probable, that, in the case related by Heister, the invagination was maintained by the union of the intestine with the corresponding part of the abdominal parietes. Several experiments on living animals have convinced him, that this happens, and that the mucous membrane will not unite with the external peritoneal coat. This impossibility of producing an immediate union between the mucous and serous membranes may of course be urged as an objection to Ramdohr's practice. (*Richerand, Nosographie Chirurgicale*, T. 3, p. 344—345, Edit. 4.) Another equally strong objection is, that the upper end of the bowel cannot be put into the lower one, unless it be separated from a part of the mesentery. Here the division of the mesenteric arteries may cause a dangerous bleeding. In vain did Boyer tie seven, or eight of these vessels: his patient died with an extravasation in the abdomen. (*Richerand*, T. 3, p. 343, Edit. 4.)

Moebius attempted to repeat Ramdohr's operation upon a dog; but, he could not succeed in insinuating the upper part of the divided bowel into the lower one, on account of the contraction of the two ends of the intestinal tube, and the smallness of the canal. Moebius, therefore, was obliged to be content with merely bringing the ends of the bowel together with a suture: the animal died, however, of an extravasation of the feces.

Dr. Smith, of the Philadelphia Medical Society, also tried to repeat Ramdohr's me-

thod, but could not succeed. He divided the intestine of a dog transversely, and having inserted a piece of candle into that portion of the bowel, which was supposed to be uppermost, he endeavoured to introduce the superior within the inferior; but, the ends became so inverted, that it was found utterly impossible to succeed. The scheme was therefore given up, and only one stitch made, the ligature being then attached to the external wound, in the manner advised by Mr. John Bell. The dog died, and, on examination, there was found a considerable quantity of feces and water in the abdominal cavity.

Two more trials were made of Mr. John Bell's plan by Dr. Smith, on the intestines of dogs: in both instances the animals died, the intestines being much inflamed, and feces effused in the abdomen. (See *Dr. Smith's Thesis.*)

Mr. Travers likewise tried the same experiment. "I divided the small intestine of a dog, which had been for some hours fasting, and carried a fine stitch through the everted edges, at the point opposite to their connexion with the mesentery. The gut was then allowed to slip back, and the wound was closed. The animal survived only a few hours. *Examination.* The peritoneum appeared highly inflamed. Adhesions were formed among the neighbouring folds, and lymph was deposited in masses upon the sides of the wounded gut. This presented two large circular orifices. Among the viscera were found a quantity of bilious fluid, and some extraneous substances, and a worm was depending from one of the apertures. By the artificial connexion of the edges in a single point of their circumference, and their natural connexion at the mesentery, they could recede only in the intervals, and here they had receded to the utmost." In another experiment, Mr. Travers increased the number of points of contact, by placing three single stitches upon a divided intestine, cutting away the threads, and returning the gut. The animal died on the second day. *Examination.* Similar marks of inflammation presented themselves. The omentum was partially wrapped about the wound; but, one of the spaces, between the sutures, was uncovered, and from this the intestinal fluids had escaped. On cautiously raising the adhering omentum, the remaining stitches came into view. Here again the retraction was considerable, and the intervening elliptical aperture proportionally large. On the side, next to the peritoneum, however, the edges were in contact and adhered, so as to unite the sections at an angle.

From such experiments, the conclusion, drawn by Mr. Travers, is, that apposition, at a point, or points, is, as respects effusion, more disadvantageous, than no apposition

at all; for, it admits of retraction, and prevents contraction, so that each stitch becomes the extremity of an aperture, the area of which is determined by the distance of the stitches. (P. 116, 119.) This gentleman, therefore, maintains, that the absolute contact of the everted surfaces of a divided intestine, in their entire circumference, is requisite to secure the animal from the danger of abdominal effusion. (P. 121.) The species of suture employed (says Mr. Travers) is of secondary importance, if it secures this contact. (P. 134.) And among other observations, I find "wounds amounting to a direct division of the canal are irreparable, and therefore invariably fatal." (P. 133.)

Without entertaining the least desire to give offence, I confess, I do not know what could induce Mr. Travers to be so positive in these inferences. We are told, that apposition at a point, or points, is, as respects effusion, more disadvantageous than no apposition at all, and that the absolute contact of the divided surfaces, in their entire circumference, is requisite to secure the animal from the danger of abdominal effusion. The foundation of these unqualified conclusions is five experiments, made on dogs, in four of which experiments, the divided bowel was brought together with one stitch, on Mr. John Bell's plan, while, in another, three stitches were made; and, yet, in all these instances, the animals died with the contents of the bowels effused. So far the inferences seem established. Unfortunately, for their stability, however, Mr. Travers immediately afterwards proceeds to relate other experiments, instituted by Mr. Astley Cooper, Dr. Thomson, and Dr. Smith, which, though Mr. Travers seems unaware of the fact, tend most completely to overturn the conclusions which he had been previously making.

"Mr. Cooper repeated the experiments of Duverger, who had succeeded, in uniting by suture, the divided intestine of a dog, including in it a portion of the trachea of a calf. In place of the uninterrupted suture, three distinct stitches were inserted. On the sixteenth day, the animal was killed, and the union was complete." (P. 123.)

Here we have two facts, proving that a wounded intestine may be united, though the suture was not such, as to maintain the divided surfaces in contact, in the whole of their circumference.

Mr. Astley Cooper then made the experiment, without including the foreign substance. The animal recovered, being a third fact, tending to shew, that the absolute contact of every point of the ends of the divided bowel is not essential to the cure. (See *A. Cooper on Inguinal and Congenital Hernia. Chap. II.*)

After dividing the small intestine of a dog, Dr. Thomson, Regius professor of Military surgery at Edinburgh, applied five interrupted stitches, at equal intervals, the ends of the ligatures were cut off, and the external wound was closed with a suture. This animal did not die of the operation, and, when he was afterwards killed, it appeared, that the threads had made their way into the interior of the intestinal canal. Dr. Thomson repeated this experiment, and did not kill the animal till six weeks afterwards, when the same tendency of ligatures to pass into the bowels, and be thus discharged, was exemplified.

These two last cases make five, in proof that the absolute contact of every part of the ends of a divided bowel is not essential to prevent effusion, or the consequences of the wound from proving fatal; and several other experiments were made by Dr. Smith, of Philadelphia, who employed four stitches, with similar success.

As far then as the majority of such facts ought to have weight, we are bound to receive the conclusions of Mr. Travers as incorrect, and unestablished. I am only surprised, that Mr. Travers himself, who has cited the particulars of all these last experiments, did not perceive, that they struck directly at his own inferences. They are not only irresistible arguments against Mr. Travers's conclusion, that the union of a divided bowel requires the contact of the cut extremities in their entire circumference; but, they are a plain denial of another position, advanced by this author, viz. that wounds, amounting to a direct division of the canal, are irreparable, and, therefore, invariably fatal.

With respect to the species of suture being of secondary importance, provided it secure the complete contact of every part of the everted ends of the divided bowel, I regret, that Mr. Travers has omitted to institute experiments, in order to show, that any such suture can be practised, and, if he has the ingenuity to apply it, whether the result would be for, or against, the conclusions, which he has formed. The fact of the sutures always making their way into the cavity of the bowel, and being thus got rid of, appears to me highly interesting, since it shews the safety of cutting away the ends, instead of leaving them hanging out of the external wound, so as to create the usual irritation and inconveniences of extraneous substances. It seems, that Mr. Benjamin Bell first recommended cutting the ends of the ligatures away, and reducing the bowel in this state into the abdomen, as he says, a considerable part of the remainder of the ligature will fall into the cavity of the gut. (*System of Surgery, Vol. II. p. 122, Edit. 7.*) We have seen,

that the experiments of Dr. Thomson confirm the observation, and those, instituted by Mr. Travers, tend to the same conclusion.

According to the latter writer, the following is the process by which a divided intestine is healed, when sutures are employed. "It commences with the agglutination of the contiguous mucous surfaces, probably, by the exudation of a fluid, similar to that, which glues together the sides of a recent flesh wound, when supported in contact. The adhesive inflammation supervenes, and binds down the everted edges of the peritoneal coat, from the whole circumference of which a layer of coagulable lymph is effused, so as to envelope the wounded bowel. The action of the longitudinal fibres, being opposed to the artificial connexion, the sections mutually recede, as the sutures loosen by the process of ulcerative absorption. During this time, the lymph deposited becomes organized, by which further retraction is prevented, and the original cylinder, with the threads attached to it, is encompassed by the new tunic.

"The gut ulcerates at the points of the ligatures, and these fall into its canal. The fissures, left by the ligatures, are gradually healed up; but, the opposed villous surfaces, so far as my observation goes, neither adhere, nor become consolidated by granulation, so that the interstice, making the division internally, is probably never obliterated." (*Travers on Injuries of the Intestine, &c. p. 128.*)

Notwithstanding I have carefully read all the arguments adduced by Mr. Travers in favour of stitching a divided bowel at as many points as possible, I still remain unconvinced of the advantage of such practice, for reasons already suggested. If a case were to present itself to me, in which a bowel was protruded and partly cut through, I should apply only a single suture, made with a common sewing needle, and a piece of fine silk. If the bowel were completely cut across, I should have no objection to attach its ends together by means of two or three stitches of the same kind. I coincide with Mr. Travers respecting the advantage of cutting off the ends of the ligature, instead of leaving them in the wound, as I believe he is right, in regard to the little chance there is of the injured intestine receding far from the wound, and if the ends of the ligature are then of no use in keeping the bowel in this position, they must be objectionable, as extraneous substances.

Sometimes, only one end of the divided gut protrudes at the wound, and the other lies concealed in the cavity of the abdomen. If the hidden continuation of the intestinal canal cannot be found without

enlarging the wound, it may be questioned, whether the urgency of the case does not justify this practice. If the upper end should happen to be the one concealed in the abdomen, almost certain death must result from its continuance there; if it be the lower one, and no attempt be made to find it, the patient can only survive with the loathsome affliction of an artificial anus.

When the protruded intestine is mortified, which must be a very rare occurrence in cases of wounds, the surgeon's conduct should be the same as in a mortified enterocoele. (See *Hernia*.)

With regard to the constitutional treatment, in wounds of the intestines, the principal indication is to prevent a dangerous degree of inflammation. Hence bleeding and the antiphlogistic treatment are highly indispensable. Let not the surgeon be deterred from putting such practice in execution by the apparent debility of the patient, his small concentrated pulse, and the coldness of his extremities, symptoms, common in acute inflammation of the bowels, and, in fact, themselves indicating the propriety of repeated venesection. Wounds of the small intestines are attended with more vehement inflammation, than those of the large ones. All flatulent, stimulating, and solid food, is to be prohibited. The bowels are to be daily emptied with glysters, by which means, no matter will be allowed to accumulate in the intestinal canal, so as to create irritation and distention.

When excrementitious matter is discharged from the outer wound, it is highly necessary to clean and dress the part very frequently. Gentle pressure should also be made, with the fingers, at the circumference of the wound, at each time of applying the dressings, for the purpose of promoting the escape of any extravasated matter. For the same reason, the patient should always lie, if convenient, in a posture that will render the external opening a depending one.

After a day or two, the surgeon need not be afraid of letting the outer wound heal up; for the adhesive inflammation, all around the course of the wound, will now prevent any extravasated matter from becoming diffused among the viscera. If the case should end well, the intestine generally undergoes a diminution in its diameter at the place where the wound was situated. When this contraction is considerable, the patient occasionally experiences colic pains at the part, especially after eating such food, as tends to produce flatulence. As these pains usually go entirely off after a certain time, and no inconvenience whatsoever remains, the intestine may possibly regain its wonted capacity again. A more considerable con-

striction of the above sort has been known to have occasioned a fatal misere. Even the intestine itself has been known to burst in this situation, after its contents had accumulated behind the contracted part. Patients, who have recovered from wounds of the intestines, should ever afterwards be particularly careful not to swallow any hard substances, or indigestible, flatulent food.

In some instances, intestinal matter continues to be discharged from the outer wound, either in part, or entirely, so that either a fistula, or an artificial anus is the consequence. A fistula is more apt to follow, when an intestine has been injured by a ball, has been quite cut though, or has mortified. But, numerous cases have evinced, that this is not invariably the consequence, and that a perfect cure has frequently followed each of these occurrences.

When an intestine is completely cut through, and the lower portion of the canal lies inaccessibly concealed in the abdomen, there is a necessity for promoting the formation of an artificial anus. In this particular case, the extremity of the intestine is to be attached, with a fine suture, to the edges of the outer wound. In order to distinguish the upper end of the intestine from the lower one, some recommend giving the patient some milk to drink, and to wait a little, to see whether the fluid issues from the mouth of the gut. In the mean while, they content themselves with applying fomentations. If the upper end of the intestine should be in the abdomen, it certainly seems justifiable, when the accident is quite recent, to dilate the outer wound sufficiently to see, whether the part is near enough to be got at. If the surgeon should succeed in this object, the two ends of the bowel ought to be sewed together, as above directed.

CONTUSIONS AND OTHER INJURIES OF THE ABDOMEN.

A violent contusion of the abdomen may injure the contained viscera, without the occurrence of any external wound. It was in this way, that the liver, or gall bladder, was ruptured in the boy mentioned by Mr. Fryer, (*Medico-Chir. Trans. Vol. 4*); and that the vena cava was lacerated in the case, which fell under the observation of Richerand, where a cart-wheel passed over a child's belly. (*Nosographie Chir. T. 3, p. 353.*) In other instances, the mischief is done to the intestines; and, still more frequently, the viscera, as well as the parietes of the abdomen, have only suffered a more or less forcible contusion. The effects of such violence are inflammation of the injured bowels, and their adhesion to the inside of the pe-

ritoneum. Thus, the stomach and intestines, the liver and the gall bladder, when inflamed from a blow upon the front of the belly, contract adhesions to the corresponding portion of the parietes, which has been also bruised and is itself inflamed. When such inflammations suppurate, (and according to Richerand it is their most usual course) on opening the abscess, the pus is found blended with the matter, which the viscera contain, or secrete. Thus, the alimentary matter, and even intestinal worms, have been discharged with the pus on opening certain abscesses, which communicated with the cavity of the stomach, or bowels; and bile has been found blended with the matter of abscesses in the right hypochondrium.

When, in consequence of a blow upon the anterior part of the belly, the patient experiences in the situation of the injury a deeply-seated pain; when a tumour forms, and the symptoms indicate violence done to some of the adjacent viscera; the inflammation is to be opposed by every possible antiphlogistic means. But, when notwithstanding such treatment, the swelling increases and suppurates, the abscess is not to be opened until it is perfectly mature. The inflammatory symptoms, which preceded its formation, indicate that there is an adhesion between the injured organ and the parietes of the abdomen. Without this adhesion, opening the abscess would be attended with more risk, because the pus, or other matter, might become extravasated in the cavity of the peritoneum. For the same reason, in the examples of tumours caused by bile in the gall bladder, J. L. Petit recommends deferring the operation of opening them, until the inflammatory symptoms evince, that an adhesion has taken place between the fundus of the gall bladder, and the corresponding point of the parietes of the abdomen.

An adhesion of the abdominal viscera to the inner surface of the peritoneum may be induced by other causes, besides the action of contusing bodies. A knife, a fork, a shoemaker's awl, a needle, and other extraneous substances, incapable of passing throughout the alimentary canal, have been known to irritate the stomach, or bowel, and to bring on adhesion of them to the parietes of the abdomen, where a tumour has formed, which on being opened has discharged the foreign body. The records of surgery abound in facts of this kind. A fistula succeeds the opening of the abscess; the alimentary matter escapes; and if the aperture admit not of being healed by methodical compression, the intestinal canal between the fistula and the anus contracts; most of the contents of the bowels pass out at the preternatural opening, and the patient falls into a state of marasmus, the more quickly fatal, the

nearer the injury of the intestinal canal is to the stomach.

A long continued pressure on the epigastric region may cause an adhesion of the stomach to the peritoneum, and suppuration taking place at the part, a fistula, communicating with the cavity of that organ, may be formed, and allow the vicinals to escape externally. (See Richerand's *Physiologie*, T. 1. *Chymification and Nosographie Chirurg.* T. 3, p. 353—356, Ed. 4.)

We shall conclude with repeating, that in the generality of injuries of the abdomen from external violence, whether wounds, or contusions, the principal danger depends upon inflammation of the peritoneum. The main object in the treatment, therefore, is to prevent and oppose this perilous affection. Repeated venesection, the application of leeches, mild aperient medicines and glysters, a low fluid diet, perfect rest, fomentations, and the warm bath, are amongst the most effectual antiphlogistic remedies, which are in such cases entitled to praise and confidence.

the conclusion of that on *Gun-shot Wounds*. Some interesting information on poisoned wounds will be found in *Catesby's Hist. of Carolina*; *Mead on Poisons*; *Fontana on the Venom of the Viper*; *Russell on Indian Serpents*; *Ireland, in Med. Chir. Trans. Vol. 2.*

WRY-NECK. (*Torticollis*.) An affection, in which the head becomes inclined to one side. The ancient writers have taken no notice of the disorder. Some of the moderns have termed it *caput obstipum*; a word, indeed, which has been employed by the best Latin authors, to denote the affliction. The wry-neck should be discriminated from the tension and stiffness of the neck, occasioned by a rheumatic affection of this part, and also from the faulty position of the head, arising from deformity in the cervical vertebræ.

Tulpius, who was a learned physician at Amsterdam, about the middle of the seventeenth century, gives an account of the cure of a boy, twelve years old, who, from his earliest infancy, had had his head drawn down towards the left shoulder, by a contraction of the scalenus muscle. Fomentations had been applied in vain, with a view of relaxing the parts, the stiffness and corrugated state of which seemed to produce the disorder. Steel-collars also proved ineffectual in bringing the head into a right posture. Tulpius had a consultation with two other skilful physicians, about the case, and it was decided to put the boy under the care of an eminent surgeon, of the name of Minnius, who had performed several operations with success in similar instances. He first made a large eschar by applying caustic, and then with a knife divided the muscle, which drew the head to one side. Tulpius, who has left only a very confused account of the operation, observes, that it was performed with great slowness and circumspection, for fear of wounding the carotid artery, and jugular vein.

The author expresses his disapprobation of this manner of proceeding, and advises such persons as will run the risk of doing so dangerous an operation not to make any preliminary application of caustic. The latter measure only caused useless pain, and could not possibly be of any service. Tulpius also recommends the operation not to be done by little and little, at repeated times; but, to make a complete division of the muscle at once, with the necessary degree of caution.

Meckren, a surgeon at Amsterdam, who has published a valuable collection of medico-chirurgical cases, also treats of the operation applicable to the wry-neck. He states, that he had seen it performed on a boy, fourteen years old. The tendon of the sterno-cleido-mastoideus muscle was divided with one stroke of a sharp pair of scissors; and in a very skilful manner, by

a surgeon named Flurianus, and as soon as the incision was made, the head took its right position. The author has also noticed the remarks made by Tulpius, relative to the plan of operating.

On approaching nearer to modern days, we find, that the celebrated Mr. Samuel Sharp considered the wry-neck as mostly arising from a contraction of the sterno-cleido-mastoideus muscle. He has proposed dividing this muscle, whenever the disorder seems to proceed from the kind of cause, which we have just now mentioned. However, he makes an exception, in regard to those cases, in which the affliction has existed a considerable time, and, particularly, in instances, in which it has prevailed from infancy. He remarks, that it would be impossible to rectify the position of the head, if the cervical vertebræ should have grown in a distorted direction. The following is the operation, which this author recommends to be done in proper cases. After placing the patient on a table, a transverse incision is to be made through the skin and fat, of a size somewhat more extensive, than the breadth of the muscle, and about one-third of its length from the clavicle. A probed-razor is then to be passed underneath the muscle, and to be drawn out, so as to make the requisite division of the part. After the incision was made, Mr. Sharp recommended the wound to be filled with dry lint, and to be always dressed in a way, that would keep the extremities of the muscle from growing together again. For this purpose, he advised the cut ends to be separated from each other as much as possible, by the assistance of a bandage to support the head, during the whole time of the cure, which, he says, will generally be about a month. (See *Treatise on the Operations of Surgery*, chap. 35.)

According to Mr. Sharp's account, the operation above described ought to be a very common one. However, if attention be paid to the nature and causes of the disease, and to the differences, resulting from whether the disorder be recent, or of long standing; constant, or periodical; idiopathic, or sympathetic; dependent on spasm, or merely on paralysis of the antagonist muscles; and, lastly, if it be recollected, that the affection may be produced by other muscles, besides the sterno-cleido-mastoideus; we shall find, that cases, in which the foregoing operation can be judiciously undertaken, are not so very frequent.

With regard to the manner in which Mr. Sharp operated, Mr. B. Bell conceived, that it was attended with hazard of wounding the large blood-vessels. But, though it seems to me better to use a probe-pointed bistoury and a director, than the kind of razor, which Mr. Sharp employed, I do not coincide with Mr. B. Bell in thinking,

that the latter surgeon's plan was at all objectionable on the score of danger, in respect to wounding the vessels. Perhaps, some might think Mr. B. Bell's method most likely to injure the large vessels; for, he advises the operator to cut the muscle from without gradually inward, as deeply as seems necessary.

Perhaps, the most prudent method of operating, is to divide the clavicular portion of the contracted muscle, near the clavicle, and even to cut out a sufficient piece, to remove all chance of the two ends uniting again. This step would weaken the muscle considerably, and, perhaps, might answer every purpose. It could easily be accomplished, by means of a director, and curved bistoury, after making the requisite division of the skin with a common scalpel. Were this proceeding only to produce a partial amendment of the wry-neck, the operator might then venture to divide the sternal portion of the muscle. A director should be passed under it, and the division made with a probe-pointed curved knife.

Although the wry-neck may occasionally depend on a contraction of the sterno-cleido-mastoideus muscle, this case is far from being very frequent. The deformity is much oftener owing to some affection of the integuments. M. Louis often divided with success contractions of the skin, which had kept the head drawn to one side for many years, and had been occasioned by burns. He remarks, that he has met with contractions of this kind, which might have been mistaken for a part of the sterno-cleido-mastoideus itself.

Mr. Gooch has related a case of wry-neck, which was caused by a contraction of the platysma myoides muscle. The patient was a young gentleman, fourteen years of age, who appeared to have always enjoyed very good health in every other respect. He had had his head, for several months, strongly drawn to one side by a constant contraction of the platysma myoides muscle, which had become exceedingly rigid, especially just where it is inserted at the basis of the jaw, and it made the skin, from the angle of the os maxillare inferius to the chin, seem like the cicatrix of a burn. The same side of the face, quite from the point of the chin, was much shrunk, and distorted by the contraction of the muscle, and the corner of the mouth, in particular, was so drawn to one side and downward, when the patient turned his head, that a vast deal of deformity was the consequence. From the inferior part of the eye-brow, at the internal angle of the eye, to near the top of the head, there was a kind of furrow upon the skin, about half an inch broad, having a shining, polished appearance, like the cicatrix of a wound, and destitute of hair,

which had fallen off. From the corner of the eye downwards, there was the same kind of appearance in a less degree. The patient was subject to repeated attacks of spasms, which began at the insertion of the muscle, and terminated at the eye, attended with a great deal of pain. The ear, and, also, the temporal and frontal muscles, were sometimes affected in a similar manner. The parts, in the course of the insertion of the muscle into the jaw-bone, were considerably thickened, without being in the least inflamed externally, and they were only a little painful, when touched, except they were at the same time stretched. The subjacent muscles did not seem to be at all affected.

It appears from the account, given by Mr. Gooch, that, in the treatment of this affection, every known means had been tried, by the advice of the most eminent practitioners; but, without effect. Mr. Gooch determined to try what benefit would be produced by dividing the muscle in the situation of the disorder. He first divided the integuments a little below the jaw, and thus exposed the whole breadth of the platysma myoides muscle, the fibres of which seemed to be in a state of violent extension, especially, when the patient's head was inclined towards the opposite side. Mr. Gooch then divided the muscle completely across, by a very careful dissection, until he had brought into view the fasciæ of the muscles underneath. The patient was then directed to turn his head towards the opposite side, and Mr. Gooch had the satisfaction of observing, that the patient could perform this motion, without his face, and corner of his mouth being affected, as they had been before. The wound was treated in the ordinary way, and no particular symptoms arose. As soon as the inflammation had subsided, the patient was directed to move his head about very frequently, in order to prevent any kind of stiffness, which might ensue, in consequence of the contraction of the muscular fibres, and inelasticity of the cicatrix.

The patient found himself perfectly relieved by the foregoing operation, and had no return of the painful spasms, to which he had been previously subject. The side of his face, however, never recovered the proper degree of plumpness.—(*Chirurgical Works of B. Gooch, Vol. 2, p. 81.*)

Whenever an attempt has been made to cure a wry-neck, by dividing any of the muscles, or merely the integuments, it becomes necessary to take some measures for keeping the head in a proper position, during the treatment of the wound, lest, in consequence of the head inclining in the direction, in which it was before the operation, the divided parts should immediately grow together again, and bring the patient almost into the same condition, in which he

was before anything had been done. With a view of preventing this unpleasant circumstance, Mr. Sharp recommends filling the wound with lint, and making it suppurate. Mr. B. Bell, on the other hand, advises the employment of a proper machine for keeping the head in a due position. Some writers think the use of a bandage quite sufficient for the purpose. Perhaps, as prudent a plan as any, when the sterno-

cleido-mastoideus is affected, is to cut out a certain portion of it. See *Sharp's Treatise on the Operations of Surgery*, chap. 35. *Chirurgical Works of B. Gooch*, Vol. 2, p. 81. *B. Bell's System of Surgery*. *Encyclopédie Méthodique*, Partie Chirurgicale, Tom. 2, Art. Torticollis. Also Dr. Joh. Christ. Gottfr. Jorg, *über die Verrkrümmungen der Menschlichen Körpers, und eine rationelle und sichere Heilart Derselben*; Leipzig, 1810.

THE END.
